Dr. William H. Weidman, consultant in pediatrics in the Mayo Clinic, Rochester, was chosen president-elect of the Midwest Society for Pediatric Research at the organization's annual meeting in Chicago.

* * *

Dr. J. W. Duncan was honored recently for his thirty-five years in the practice of medicine in Moorhead by the Franciscan Sisters who operate the St. Ansgar Hospital.

* * *

Dr. Robert R. Kierland, head of the section of dermatology in the Mayo Clinic, was elected first president of the Dermatology Foundation, at the meeting of the board of trustees of the organization.

* * *

Dr. Merle S. Mark has been selected chief of the medical staff at Glenwood Hills Hospital in Minneapolis. **Dr. John W. Lawrow** was selected vice chief-of-staff and president-elect with **Dr. Walter Indeck** named secretary and treasurer.

* * *

Dr. Alton C. Olson, president of the Eitel Hospital medical staff, recently announced the officers of the Hospital. **Dr. Thomas M. Recht** was named chief-of-staff, and **Dr. Richard E. Anonsen**, assistant chief-of-staff, for a second term. **Dr. Marie Moorhead** was also named secretary-treasurer.

* * *

Dr. H. O. Morgan of Amboy has practiced medicine in that community for thirty years, and the entire town extended its congratulations to Dr. Morgan.

* * *

Dr. Fred A. Lyon of St. Louis Park will be installed as a fellow of the American College of Obstetricians and Gynecologists at its annual meeting in May in Chicago.

* * *

Dr. Ormond S. Culp, head of the Section of Urology in the Mayo Clinic, was elected president of the Clinical Society of Genito-Urinary Surgeons at its meeting recently, and **Dr. James T. Priestley**, head of a section of surgery at the Mayo Clinic, has been appointed a special consultant on the Clinical Research Training Committee of the National Institute of General Medical Sciences.

* * *

Dr. F. T. Becker is the newly named chief-of-staff of St. Mary's Hospital in Duluth. Other hospital staff members named were: **Dr. I. T. Clark**, chief of staff-elect, and **Dr. H. J. Meyer**, secretary.

* * *

Dr. David G. Smith of Watertown, **Dr. Theodore P. Myers** of Albert Lea and **Dr. Oliver Elwood Wiger** of Little Falls have been elected to active membership in the American Academy of General Practice.

* * *

Dr. Sumner Cohen has succeeded **Dr. Maxwell Barr** as president of the Mount Sinai Hospital staff in Minneapolis. Others elected to the medical staff include: **Dr. Jules Feinstein**, president-elect, and **Dr. Donald Fingerman**, secretary-treasurer.

* * *

Dr. Vincent Hunt of Red Lake Falls was elected president of the Red River Valley Medical Society at its mid-winter meeting, and **Dr. Cliff Stadem** of Fertile was elected vice president. **Dr. R. O. Sather** of Crookston was elected secretary.

* * *

Dr. Roger W. Brockway of Grand Rapids was installed president of the Range Medical Society at its annual meeting in January. **Dr. H. Wayne Johnston** of Virginia was installed as president-elect; **Dr. Kenneth A. Ahola** of Hibbing, vice-president and **Dr. Douglas J. Coy** of Grand Rapids, secretary-treasurer.

* * *

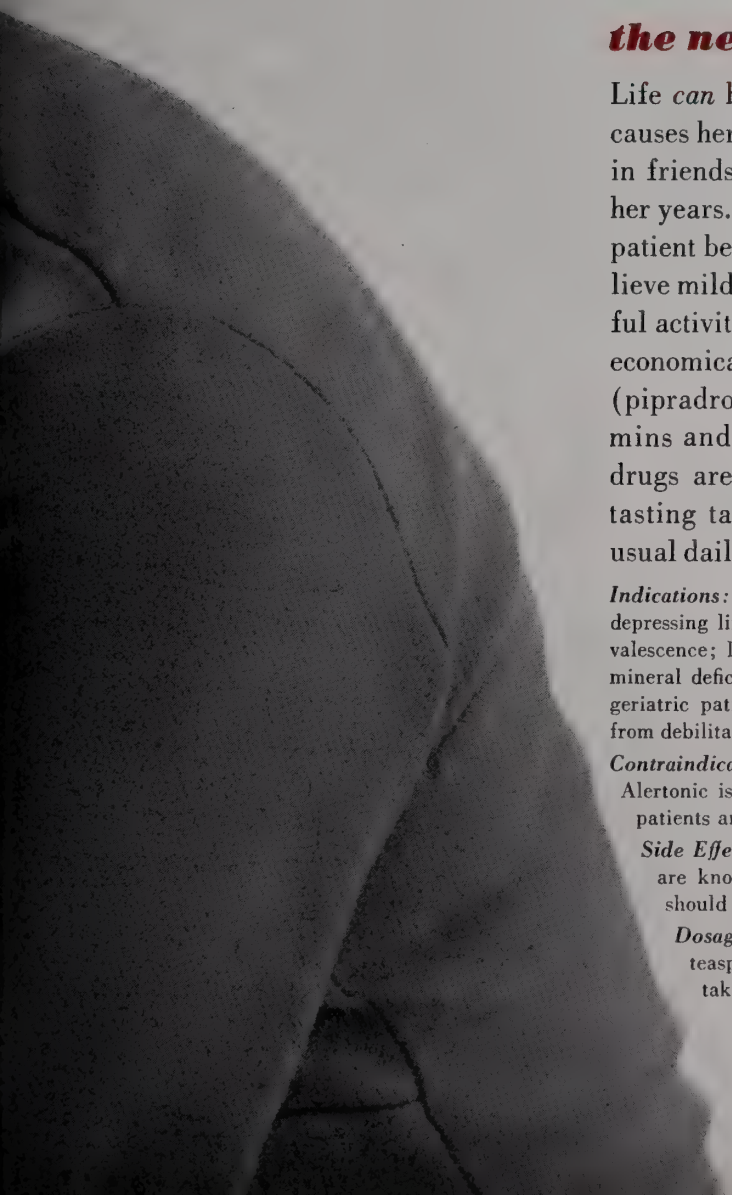
Dr. Robert V. Hodapp of Willmar, has been elected to a fellowship in the American Academy of Pediatrics at its recent annual meeting.

too young
to be so tired...

revive interest...restore activity promptly with Alertonic®

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B_1) (10 MDR*), 10 mg.; riboflavin (vitamin B_2) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B_6), 1 mg.; niacinamide (5 MDR), 50 mg.; choline†, 100 mg.; inositol†, 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.
†The need for these substances in human nutrition has not been established.



the need for a tonic knows no age

Life *can* begin at forty—except when functional fatigue causes her to feel tired all the time; to start losing interest in friends and surroundings; to look and act older than her years. Alertonic—*a prescription tonic*—can help your patient become her normal self again. Alertonic helps relieve mild depression, revive interest and restore purposeful activity promptly...with a formula that is efficient *and* economical. Alertonic contains a mild central stimulant (pipradrol hydrochloride), 15% alcohol, essential vitamins and minerals. No hormones or MAO-inhibiting drugs are included. No iron. No iodine. One pleasant-tasting tablespoonful before each meal comprises the usual daily dose.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Contraindications: As with other drugs with CNS-stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive-compulsive states.

Side Effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

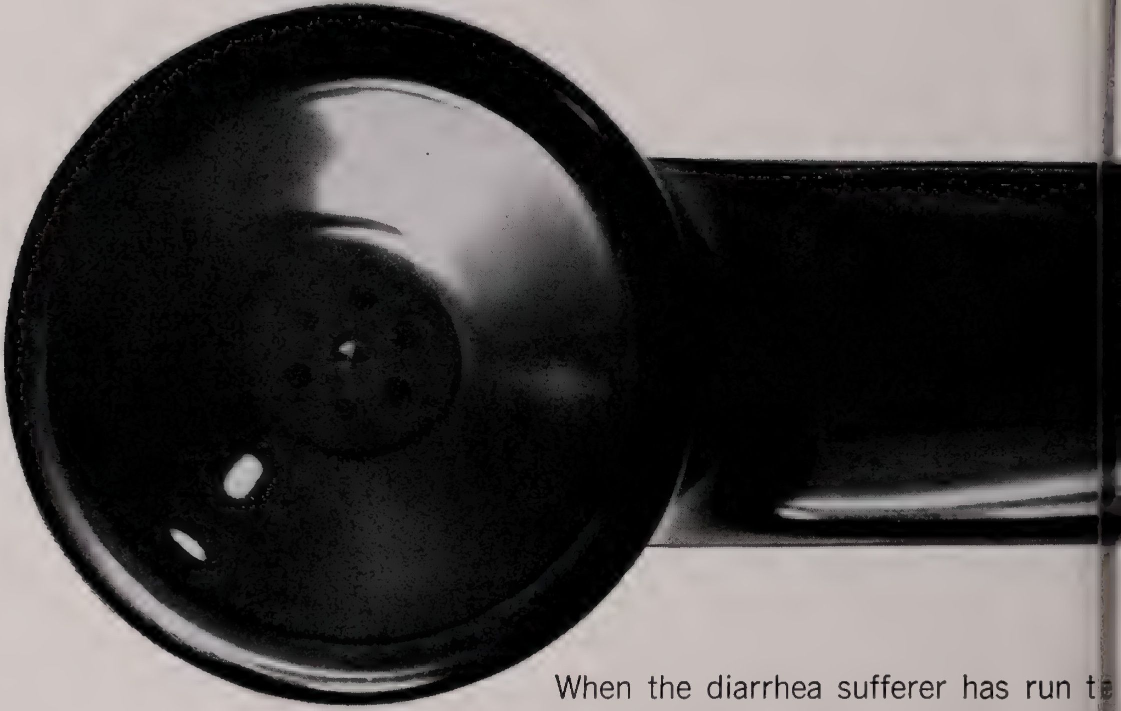
When uncontrolled diarrhea brings a call for help



When the diarrhea sufferer has run t gamut of home remedies without succes pleasant-tasting CREMOMYCIN can answ the call for help. It can be counted on consolidate fluid stools, soothe intestin inflammation, inhibit enteric pathogen and detoxify putrefactive materials—us ally within a few hours.

CREMOMYCIN combines the bacteriosta agents, succinylsulfathiazole and neom cin, with the adsorbent and protective c mulcents, kaolin and pectin, for compr hensive control of diarrhea.

Indications: Diarrhea. *Contraindications:* Kaol Withhold if diverticulosis is present or suspect *Precautions:* Sulfonamide: Continued use requi supplementary administration of thiamine and v

your ℞ for
Cremomycin
can provide relief

in K. Neomycin: Patient should be observed for w infections due to bacteria or fungi. *Side Effects:* ulfonamide: Sensitivity reactions may occur (e.g., in rashes, anemia, polyneuritis, fever; agranulotosis with a fatal outcome has been reported). eduction of thiamine output in the feces and of amin K synthesis has been observed. Neomycin: ausea, loose stools possible.

efore prescribing or administering, read product rcular with package or available on request.

romptly relieves diarrheal distress

Cremomycin®

NTIDIARRHEAL

mposition: Each 30 cc. contains neomycin sulfate 0 mg. (equivalent to 210 mg. of neomycin base), ccinylsulfathiazole 3.0 Gm., colloidal kaolin 3.0 n., pectin 0.27 Gm.

MERCK SHARP & DOHME Division of Merck & Co., Inc., West Point, Pa.

here today's theory is tomorrow's therapy

now...introducing a new high-strength dosage f

SIGNEM

A 'MAXIMUM SECURITY' ANTIBIOTIC*

- ✻ THE BROAD RANGE DEPENDABILITY OF TETRACYCLINE
  long established as the broad-spectrum agent of first choice in a wide variety of infections
- ✻ WITH THE ADDED SECURITY OF MEDIUM-SPECTRUM REINFORCEMENT
  triacetyloleandomycin is highly active against the common 'coccal' pathogens, including certain strains of staphylococci resistant to penicillin and tetracycline
- ✻ ESPECIALLY VALUABLE IN U.R.I.
  provides decisive therapy in acute respiratory infections and other conditions in which staphylococci, streptococci or mixed flora are frequently encountered
- ✻ NOW AVAILABLE IN NEW STRENGTH FOR NEW CONVENIENCE AND ECONOMY
  Signemycin 375—high-potency capsules for simpler administration, greater patient economy

YCIN® 375

(tetracycline 250 mg.
triacetyloleandomycin 125 mg.)

Indications: Indicated in the therapy of acute severe infections caused by susceptible organisms and primarily by bacteria more sensitive to the combination than to either component alone. In any infection in which the patient can be expected to respond to a single antibiotic, the combination is not recommended. Signemycin should not be used where a bacteriologically more effective or less toxic agent is available. *Triacetyloleandomycin, a constituent of Signemycin, has been associated with deleterious changes in liver function.* See precautions and adverse reactions.

Contraindications: Contraindicated in individuals who have shown hypersensitivity to any of its components. Not recommended for prophylaxis or in the management of infectious processes which may require more than 10 days of continuous therapy. If clinical judgement dictates therapy for longer periods, serial monitoring of liver function is recommended. Not recommended for subjects who have shown abnormal liver function tests, or hepatotoxic reactions to triacetyloleandomycin.

Precautions and Adverse Reactions: Triacetyloleandomycin, administered to adults in daily oral doses of 1.0 gm. for 10 or more days, may produce hepatic dysfunction and jaundice. Adults requiring 3 gm. of Signemycin initially should have liver function followed carefully and the dosage should be reduced as promptly as possible to the usual recommended range of 1.0 to 2.0 gm. per day. Present clinical experience indicates that the observed changes in liver function are reversible after discontinuation of the drug. Use with caution in lower than usual doses in cases with renal impairment to avoid accumulation of tetracycline and possible liver toxicity. If therapy is prolonged under such circumstances, tetracycline serum levels may be advisable. In long term therapy or with intensive treatment or in known or suspected renal dysfunction, periodic laboratory evaluation of the hematopoietic, renal and hepatic systems should be done. Formation of an apparently harmless calcium complex with tetracycline in any bone forming tissue may occur. Use of tetracycline during tooth development (3rd trimester of pregnancy, infancy and early childhood) may cause discoloration of the teeth. Reversible increased intracranial pressure due to an unknown mechanism has been observed occasionally in infants receiving tetracycline. Glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and definite allergic reactions occur rarely. Severe anaphylactoid reactions have been reported as due to triacetyloleandomycin. Photosensitivity and photoallergic reactions (due to the tetracycline) occur rarely. Medication should be discontinued when evidence of significant adverse side effects or reaction is present. Patients should be carefully observed for evidence of overgrowth of nonsusceptible organisms including fungi, which occurs occasionally, and which indicates this drug should be discontinued and appropriate therapy instituted. Steps should be taken to avoid masking syphilis when treating gonorrhea.

Lederle
BAMADEX
DEXTRO-AMPHETAMINE SULFATE
WITH MEPROBAMATE
SEQUELS
Sustained Release Capsules
077 619

By providing combined anorexigenic-tranquilizing action, BAMADEX SEQUELS Capsules help your nonshrinking patients to establish new patterns of eating less. The amphetamine component suppresses the appetite, while the meprobamate helps allay nervousness and tension. And for most patients, the *sustained* release of the active ingredients provides convenient one-capsule-a-day dosage.

Side Effects commonly associated with either component are possible but, to the extent these are dose-related, they should normally be mild and infrequent, since the total dosage of each component on the usual one-capsule-daily regimen is quite low. Also, the sedating effect of meprobamate and the stimulating effect of d-amphetamine sulfate tend, to some extent, to cancel each other out. Adverse effects not peculiar to either component have not been reported. Side effects associated with d-amphetamine sulfate include: insomnia, excitability, increased motor activity, confusion, anxiety, aggressiveness, increased libido, hallucinations, rebound fatigue, depression, dry mouth, anorexia, nausea, vomiting, diarrhea and increased cardiovascular reactivity. Effects associated with meprobamate include: skin rash, nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema, fever and transient leukopenia; also, very rarely, fainting spells, angioneurotic edema, bronchial spasm, hypotensive crisis, anuria, stomatitis, proctitis and anaphylaxis. Other serious effects have occurred after concomitant administration of meprobamate and other drugs. Massive overdosage may produce grave effects.

Precautions: BAMADEX SEQUELS should be given only under close supervision to patients hypersensitive to sympathomimetic drugs, with cardiovascular or coronary disease or who are severely hypertensive; to emotionally unstable persons and to epileptics. Patients should be cautioned not to drink alcoholic beverages while on the drug, and not to drive vehicles if they become drowsy. In all patients kept on the drug for long periods, the drug should be withdrawn gradually to avoid possible serious reactions.

Contraindications: Hyperexcitability, agitated prepsychotic states and a history of previous reactions to meprobamate.

Bamadex® Sequels®

d-amphetamine sulfate (15 mg.) and meprobamate (300 mg.)

Minnesota Medicine at a Glance

Hearing Problems — Hilger Page 561

For the doctor who must attend to a great variety of disease processes pertaining to the ears, Hilger has detailed many procedures and diagnostic methods which can be readily applied in the office of one who is equipped to deal with them. From a review of this manuscript one can no doubt improve his office handling of numerous ear problems.

Aortoiliac Occlusion — Monge′ and LaBree Page 566

Aortoiliac occlusion can usually be diagnosed clinically on the basis of claudication in the hip, thigh, or calf. There may be marked ischemia and a diminution or absence of pulsation at the femoral artery in the groin. Translumbar aortography or distal arteriograms confirm the diagnosis in a high percentage of cases, and this procedure is useful in aiding the surgeon in making an evaluation of the proper operative procedure in advance of the exploration.

A bypass prosthetic graft proved to be the most successful technique for relieving aortoiliac occlusion, and though the incidence of subsequent major sequellae is high, this procedure offers some hope for those who might otherwise suffer almost total disability.

Small Bowel Tumors — Scott and Grossling Page 572

Primary small bowel tumors occur so infrequently as to be unsuspected in many instances when a patient's symptom is that of anemia with an unexplained origin. It would be well to review this manuscript in order to recall to mind that the most common clinical feature is that of gastrointestinal bleeding, obstruction, abdominal pain, and a palpable mass.

X-ray examination is capable of providing diagnostic suspicion in approximately one third of the cases.

Lupus Erythematosus — Dubnow et al. Page 577

Abdominal pain may be a symptom of systemic lupus erythematosus. Rarely is this pain sudden and severe enough to simulate an acute surgical emergency. If leukopenia, anemia, and abnormal urinary constituents are present, systemic lupus erythematosus should be considered, and appropriate confirmatory studies made.

An interesting and pertinent article calling attention to an unusual facet of a not uncommon disease. The writer implies but does not substantiate that the proper treatment is intestinal resection.

Salmonella Pullorum Septicemia — ten Bensel and Williams Page 580

Salmonella organisms are known to be widely distributed in animals; but rarely do they infect man. Chickens infected with *Salmonella pullorum* are a constant concern to public-health authorities, as these asymptomatic birds may be producing eggs which are contaminated and which may subsequently infect man. Minnesota is fortunate in having a low incidence of infected birds; but from the case report of ten Bensel and Williams it is apparent that those few are a real and constant threat to man. Their patient apparently acquired *Salmonella pullorum* septicemia from eating raw eggs; certainly his underlying disease process rendered him more susceptible to this infection. Even though this is the first reported fatal case of *Salmonella pullorum* infection it is pointed out that the physician must take great care in the feeding of raw eggs, undercooked eggs or dried egg products until such time as these are known to be free of salmonellae.

Hepatolobectomy for Metastatic Neuroblastoma

— Brown and Hart Page 591

Partial hepatolobectomy has been performed more frequently in the past few years for benign lesions, and in a few instances total hepatolobectomy has been done. For a child with neuroblastoma a hepatolobectomy was successfully done, though in this instance considerable morbidity was encountered and the child finally died at the end of about a year. It is of interest to note that roentgen therapy was able to reduce the size of the mass in the liver from an inoperable lesion to one that could be removed.

Neoplasms of the Nasopharynx — Medical Seminar Page 635

This discussion of nasopharyngeal tumors indicates the complexities and difficulties in differential diagnosis. When more than one cranial nerve is involved, the diagnosis sometimes is more readily arrived at from a clinical consideration rather than by extensive diagnostic procedures. However, occasionally nasopharyngeal lesions will be overlooked because the clinical picture suggests a tumor of the jugular bulb rather than a nasopharyngeal malignancy. A careful nasopharyngeal examination is extremely important and should be recommended before intracranial exploration of the jugular bulb is attempted.

Alcoholics — Heart Disease — Grand Rounds Page 653

Heart disease has a variety of causes, and in most instances the etiologic factors, which include coronary artery disease, hypertension, and various toxic and infectious processes, become evident after a short period of evaluation.

The more unusual causes for heart disease, which are not as readily evident, may be accurately diagnosed if one keeps in mind that heart disease can result from malnutrition leading to thiamine deficiency, and can also be accounted for in a similar manner in a chronic alcoholic. The case reports detailed in the Grand Rounds are worth a total review.

Manifestations of Cancer — Nuessle Page 659

The systemic manifestations of malignant neoplasms are presented in considerable detail. Awareness of these manifestations, such as thrombophlebitis, hypoglycemia, hypercalcemia, hyperuricemia, erythrocythemia et cetera, along with the knowledge that such entities as dermatomyositis, acanthosis nigricans, Peutz-Jegher's syndrome and herpes zoster, may indicate an underlying malignant neoplasm and will help the clinician in earlier detection of cancer.

Special Issue

INDICATIONS: Grand mal epilepsy and certain other convulsive states.
PRECAUTIONS: Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced.
SIDE EFFECTS: Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Upon discontinuation of therapy eruptions usually subside. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Though mild and rarely an indication for stopping dosage, gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered, especially in children, adolescents, and young adults. During initial treatment, minor side effects may include gastric distress, nausea, weight loss, transient nervousness, sleeplessness, and a feeling of unsteadiness. All usually subside with continued use. Hematologic disorders, including megaloblastic anemia, leukopenia, granulocytopenia, pancytopenia, and aplastic anemia have been reported. Nystagmus may develop.
DILANTIN is supplied in several forms including Kapseals containing 0.1 Gm. and 0.03 Gm. diphenylhydantoin sodium.

when pain is beyond the reach
of simple analgesics

In the management of mild to moderate pain, give your patients comprehensive relief. TRANCO-GESIC extends the range of usefulness of aspirin by dimming pain perception—and *also* reducing mental and muscle tension.

TRANCO-GESIC®

tablets

chlormezanone 100 mg. with aspirin 300 mg.

subdues the major contributors to pain:

- pain perception
- mental tension
- muscle tension-spasm

TRANCO-GESIC is so well tolerated it can be prescribed for anyone who can take aspirin. It is non-narcotic, and free from dangers of addiction, habituation, or dependence. TRANCO-GESIC is effective in all types of mild and moderate pain. Of 862 patients who were treated with chlormezanone and aspirin for various disorders, 88% reported excellent or good pain relief.[1]

Side effects have been minor. Occasionally gastric distress, weakness, sedation or dizziness occur. Reversible cholestatic jaundice has been reported on rare occasions. However, in 4,653 patients treated with chlormezanone, 97.7% had *no* side effects.[1] *Contraindication:* just one: sensitivity to aspirin. *Dosage:* Adults, usually 2 tablets three or four times daily. Children (from 5 to 12 years), 1 tablet three or four times daily.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Advertisers and Subscribers

Display advertising rates on request. Classified advertising rates appear on classified page.

Annual Subscription—$6.50. Single copies—$1.00. Foreign and Canadian—$7.50.

Communications concerning advertising and subscriptions should be addressed to Minnesota Medicine, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Telephone CApital 4-5738.

New 300 mg tablet It's made for b.i.d.

For Adults–2 tablets provide a full 24 hours of therapy...with all the extra benefits of DECLOMYCIN...lower mg intake per day...proven potency... 1-2 days' "extra" activity to protect against relapse or secondary infection.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE
300mg FILM COATED TABLETS

Effective in a wide range of everyday infections —respiratory, urinary tract and others—in the young and aged—the acutely or chronically ill—when the offending organisms are tetracycline-sensitive.

Warning — In renal impairment, usual doses may lead to excessive systemic accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photo-allergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of discomfort.

Precautions and Side Effects — Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. Use of demethylchlortetracycline during tooth development (last trimester of pregnancy, neonatal period and early childhood) may cause discoloration of the teeth (yellow-grey-brownish). This effect occurs mostly during long-term use but has also been observed in short treatment courses. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment. Side reactions include glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and dermatitis. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Anaphylactoid reactions have been reported.

Contraindication—History of hypersensitivity to demethylchlortetracycline.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products.

Capsules: 150 mg of demethylchlortetracycline HCl.

Tablets: film coated, 300 mg, 150 mg, and 75 mg of demethylchlortetracycline HCl.

President's Letter

Recently the American Medical Association, through the Council on Drugs, announced the development of a Registry on Adverse Reactions. The announcement is also an appeal to individual physicians to report, on forms, supplied on request directed to the Registry, all adverse reactions to any therapy observed in individual patients.

Cooperation by physicians is to physician advantage; for by the sheer weight of individual reports, otherwise unidentified reactions will be recorded, classified, and taped as a living, growing compilation, to identify the rare cases and report any suggestive trends in unexpected results, as well as the frequency of those results.

No problems exist in the area of confidentiality, for all reporting physicians are identified simply by code, and only with a physician's consent will his name be revealed in the event further educational study is indicated.

The patient in turn will be identified only by initial, date of birth, sex and race; and in any scientific exchange program the identity of the patient, the physician and the hospital remains confidential.

Legal opinion supports the position that no risk is involved in reporting adverse reactions. No liability for negligence can be incurred by either physician, hospital or other reporting group.

Recalling that hospitalized patients who have unexpected results from any therapeutic measures have, in those hospitals where adequate clinical records are kept, a fully recorded description of such unexpected results, a registry is in actuality only an extension of such a record. The implications in this American Medical Association endeavor are obvious.

Since the program is essentially an educational one, conclusions, warnings and suggestions will be made available to physicians through professional media. In addition, individual problems will be considered and individual assistance provided by panels of outstanding consultants, on a personal basis to those physicians requesting information and advice from the registry.

This request, an invitation to participate in a purely medical program of distinct benefit to patient and physician alike, refreshingly free of any of the political implications so prominent in recent and continuing medical activity, deserves the cooperation and interested participation of every physician.

This issue of MINNESOTA MEDICINE is dedicated to Dr. Gerald T. Evans, Professor and Head of the Department of Laboratory Medicine of the University of Minnesota. Dr. Evan's brilliant and productive career in Clinical Laboratory Medicine, his many contributions, his untiring efforts to produce quality-controlled laboratory procedures should be an example for each of us to make our individual contribution, as requested by the Registry, to this lesser but significant area of progress in medicine.

Low host resistance?

Consider the "extra" antibacterial activity of Ilosone®

Occasionally, therapeutic failure is due to the patient's inability to mobilize his defenses sufficiently to overcome infection. Typical of this is the debilitated patient, the premature infant, or the diabetic. It is in these patients that the high levels of antimicrobial activity of Ilosone are especially useful. Ilosone has demonstrated antibacterial levels two to four times those of erythromycin base or stearate. Furthermore, it attains them earlier and maintains them longer. Even the presence of food does not appear to affect the activity of Ilosone.

Contraindications: Ilosone is contraindicated in patients with a known history of sensitivity to this drug and in those with preexisting liver disease or dysfunction.

Side-Effects: Even though Ilosone is the most active oral form of erythromycin, the incidence of side-effects is low. Infrequent cases of drug idiosyncrasy, manifested by a form of intrahepatic cholestatic jaundice, have been reported. There have been no known fatal or definite residual effects. Gastro-intestinal disturbances not associated with hepatic effects are observed in a small proportion of patients as a result of a local stimulating action of Ilosone on the alimentary tract. Although allergic manifestations are uncommon with the use of erythromycin, there have been occasional reports of urticaria, skin eruptions, and, on rare occasions, anaphylaxis.

Dosage: *Children under 25 pounds*—5 mg. per pound of body weight every six hours. *Children 25 to 50 pounds*—125 mg. every six hours. *Adults and children over 50 pounds*—250 mg. every six hours. For severe infections, these dosages may be doubled.

Available in Pulvules®, suspension, drops, and chewable tablets. Ilosone Chewable tablets should be chewed or crushed and swallowed with water.

OUR VIEW OF the lymphoid system of tissues and cells has undergone rapid revision during the last few years and is still in a period of redefinition. Any current concept is necessarily a partial one and subject to modification as new clinical and experimental evidence becomes available. There are two basic divisions we should like to consider. The first distinction we see is that of *central* versus *peripheral* lymphoid tissue. The prototype of a central lymphoid tissue is the thymus, an organ originating in the epithelium of the gut, a "source" tissue in the ontogenesis of most of the rest of the lymphoid system, and an important factor in immunogenesis, lymphoreticular malignancy, and "auto-immunity." The bursa of Fabricius of the chicken and the appendix of the rabbit are also in this category; other tissues of this type undoubtedly exist, particularly in higher mammals. The prototype of a peripheral lymphoid tissue is the spleen (and in mammals, the lymph nodes), dependent on central lymphoid tissue in late embryonic and early postnatal life, but relatively autonomous in the mature organism.

The second division is one which has been implicit in a number of clinical observations during the last year or two, but which has only recently been demonstrated in an experimental model in the chicken. The data suggest that there are two lymphoid systems in a sense, one dependent on the thymus and thymus-like central lymphoid tissue, and the other dependent on the bursa (in chickens) and bursa-like central lymphoid tissue or tissues in mammals. The cell type typical of the thymus-dependent lymphoid development is the small lymphocyte; the cell type

typical of the bursa-dependent lymphoid development is the plasma cell. Functionally, the thymus-dependent system seems to represent immunologic recognition. In responses of the delayed hypersensitivity type it is apparently also the effector system; in responses of the circulating antibody type it apparently passes "information" to the other system which actually produces the immunoglobulins.*

Types of Immunologic Deficiency

On this basis, we can classify two types of immunologic deficiency and two types of lymphocytic malignancy, depending on the system of cells involved.

Thymus-Based Immunologic Deficit

The immunologic depression produced in mice, rabbits, rats, and hamsters by neonatal thymectomy (or, in the case of rabbits, by thymectomy and/or appendectomy) has affected recognition; these animals may have extremely deficient reactions of delayed hypersensitivity and transplantation immunity, but have normal numbers of plasma cells and normal levels of immunoglobulins. In the chicken a similar model is produced by thymectomy and sublethal irradiation in the immediate post-hatching period. All of them are deficient in specific antibody production, however, because the recognition system is awry. Consistent with this view is the finding that neonatally thymectomized mice and rabbits often have Coombs-positive red blood cells and organic lesions of the "auto-immune" type.

Agammaglobulinemia

The second type of immunologic defect is that found in the sex-linked recessive type of agammaglobulinemia in humans and also in chickens subjected to bursectomy and sublethal irradiation in the immediate post-hatching period. Neither these patients nor these chickens produce detectable antibody on repeated stimulation; however, there is every evidence that they recognize "foreignness" and are able to express cellular immunity. The experimental model of agammaglobulinemia is still being defined. We recently reviewed in some detail the pathogenesis of immunologic deficiency diseases in the context of the recent experimental work on the two systems.[21]

Reevaluation of Lymphoid Malignancies

Redefinition of both experimental and clinical lymphoid malignancies is indicated.

Bursa and Thymus-Dependent Experimental Lymphoma

The typical thymic lymphoma of mice is an ideal example of a thymus-dependent neoplasm; visceral lymphomatosis in the chicken is an ideal example of a bursa-dependent lymphoma. Removal of the appropriate tissue early in life almost completely prevents the occurrence of these malignancies.[12,15]

Clinical Lymphomas

Our knowledge of the range of immunologic deficiency in Hodgkin's disease[22] suggests that thymus or at least thymus-system involvement is basic in this disease, the thesis advanced in England some years ago by Thomson[23] on pathologic grounds. Giant follicular lymphoblastoma is the human disease most remindful of the follicular enlargement observed in chickens with visceral lymphomatosis, and it is of great interest that several patients developing acquired agammaglobulinemia have had a benign form of lymphoid hyperplasia of this type concurrently.

Some acute and chronic lymphatic leukemias seem to represent even in their initial stages involvement of the small lymphoid cells, those of the thymus-dependent system; plasma cell myeloma, of course, involves primarily the immunoglobulin system. We believe that the initial involvement in lymphoid malignancies is in only one of the cell systems, and that the immunologic status of the experimental animal or patient is sometimes indicative of the component involved very early in the disease. Much more work is needed on this problem even to suggest what the implications of this division are for diagnosis and treatment in human disease.

---

*The bibliography (references 1-20) lists two books, several reviews, and a number of basic individual research reports on the recent thymus-bursa work and its historical background.

Discussion

In ontogenetic development (and in cases of extreme lymphoid tissue depletion later in life) it seems probable that both of these tissues function both as a source of cells and of humoral substances which foster lymphoid cell development and maturation of immunologic competence.[17,24-27] The essential defect is at the peripheral level, however, and it seems, at least in the case of the mouse thymus, that the stroma is not essential if a sufficient number of histocompatible lymphoid cells can be provided the neonatally thymectomized animal by intraperitoneal injection.

Auto-Immunity

Woven through much of the current literature and discussion of the thymus is the concept of auto-immunity: that thymic abnormalities are associated with clinical and experimental syndromes characterized by serologic and pathologic manifestations often grouped as "auto-immune" phenomena. Thus, germinal center development and plasma cells have been observed in the thymuses of patients with myasthenia gravis, lupus erythematosus, and thyrotoxicosis, in which one or more auto-antibodies are usually found in the circulation. Similar lesions have been observed in the NZB/BL mice, an inbred strain with a very high incidence of Coombs-positive anemia.[28] Coombs positivity is also seen in some strains of neonatally thymectomized mice[29] and in rabbits subjected to neonatal thymectomy or appendectomy-thymectomy.[30] Neonatally thymectomized mice, observed by deVries and his colleagues[29] in Holland, have had LE-like lesions of the heart and kidney as well as abnormal antibodies. We have been especially attracted to the relation of auto-immunity to immunologic deficiency in view of our own experience and that of other clinical groups that agammaglobulinemic patients have an unusually high incidence of "auto-immune" diseases; since they form virtually no antibody of any kind, these patients have the disease without the customary auto-antibodies. The most obvious unifying concept, of course, is that we are dealing with virus or mycoplasma infections, and that any form of immunologic deficiency is likely to favor the development of clinical disease. Blunted immunologic recognition might also favor abnormal antibody formation to self-constituents in damaged tissues, a development which might in turn result in further tissue destruction.

Addendum

In preliminary experiments, humoral immunity has been selectively depressed in rabbits by removal of the appendix, sacculus rotundus, and Peyer's patches. This has been done by removing the tissue in newborn animals, and by removing the tissue at a later age and irradiating the rabbits. Cellular immunity remains intact in both instances.

The Penalty of Overweight

There is widespread agreement that mortality and morbidity from cancer are increased in the presence of obesity.

— Cyril M. MacBryde, M.D., Signs & Symptoms, Lippincott Co.

Human Serum

In 1950 Gould and Taylor reported a marked suppression of newly synthesized cholesterol in the liver and plasma of dogs ingesting a high cholesterol diet[1] (Figure 1), and others demonstrated a similar homeostatic mechanism in rats.[2] The mechanism of this inhibition of cholesterol synthesis by dietary cholesterol has been studied extensively and shown to possess the characteristics of a negative "feed-back" mechanism or control system. Thus, in this control system, a single reaction, the reduction of Beta-OH Beta methyl glutaryl CO A to mevalonic acid, was shown to be the primary site of depression of cholesterologenesis produced by exogenous (dietary) cholesterol.[3] Studies in our laboratories have shown an almost complete lack of change in the rate of appearance of newly synthesized plasma cholesterol in man regardless of the type of diet employed (cholesterol-rich or cholesterol-low)[4] (Figure 2). These findings corroborated earlier studies which indicated that man (unlike the dog and rat) has little demonstrable "feed-back" control of in vitro hepatic cholesterol synthesis.[5]

Employing an indirect method for estimating relative contributions of dietary and endogenously synthesized cholesterol to plasma cholesterol (reported by Morris and others in studies on rats[6]), we fed ring-labeled 4-C^{14} cholesterol to dogs and humans.[7,8] Our studies in the dog were comparable to those reported in the rat by Morris and others; both animals demonstrated nearly complete replacement of endogenous sources of plasma cholesterol by ring-labeled dietary cholesterol (Figure 3). The indirect studies were in good agreement with earlier studies demonstrating the dominant homeostatic role played by the liver in the cholesterol metabolism of the rat and the dog. The

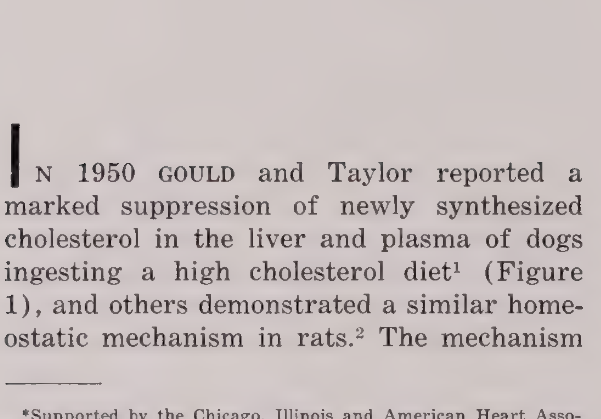

Fig. 1 — Effect of dietary cholesterol on in vitro cholesterol synthesis by liver slices in dogs. Estimated mg. of cholesterol synthesis per 100 gm. liver are plotted on the ordinate; hours incubated in presence of C^{14} acetate are plotted on the abscissa. Control dogs were on cholesterol-free diets before liver biopsies were taken for incubation. Cholesterol-fed dogs were fed 1 gm. cholesterol in oil 12 hours before liver biopsies were taken for incubation. Estimations of cholesterol synthesis were determined from quantities of C^{14} acetate incorporated into cholesterol molecules isolated from incubated liver slices.

D. T. FORMAN, Ph.D.**
GARY FRANZ, B.S.**
Evanston, Illinois

results from the ring-labeled cholesterol feeding studies in man were very different from those observed in dogs and rats. Only about a quarter to a third of labeled dietary cholesterol appeared in plasma with the remaining large fraction of ¾ to ⅔ of plasma cholesterol apparently being derived from endogenous synthesis (Figure 4). Since most subjects showed a rise in serum cholesterol while on the ring-labeled cholesterol regimen, there is suggestive evidence that, in the human, dietary cholesterol is added to an essentially quantitatively unaltered endogenous supply of plasma cholesterol.[8]

To better understand cholesterol metabolism in man and to determine the effects of dietary cholesterol on the rate of synthesis of serum cholesterol a deuterium labeling technique was employed. The rationale and methods were based on the work of London and Rittenberg (1950), who showed that a single adult male subject on a regular diet (probably containing 0.5 to 1 gm. of cholesterol per day) had about 0.5 gm. of newly synthesized cholesterol appear in his plasma each day.[9] Since much of the quantitative estimation of human cholesterol synthesis is based on this study, we felt the need for similar studies with subjects on cholesterol-free and cholesterol-rich diets.

Methodology

Eight endogenous serum cholesterol synthesis studies were carried out on five healthy human subjects (male and female). The subjects' age, race, sex and national origin varied considerably. Each subject served as his or her own control and they were alternately placed on a cholesterol-low diet and cholesterol-rich diet. The cholesterol-low diet consisted mainly of egg whites, beans, lentils, powdered fat-free milk and dry cottage

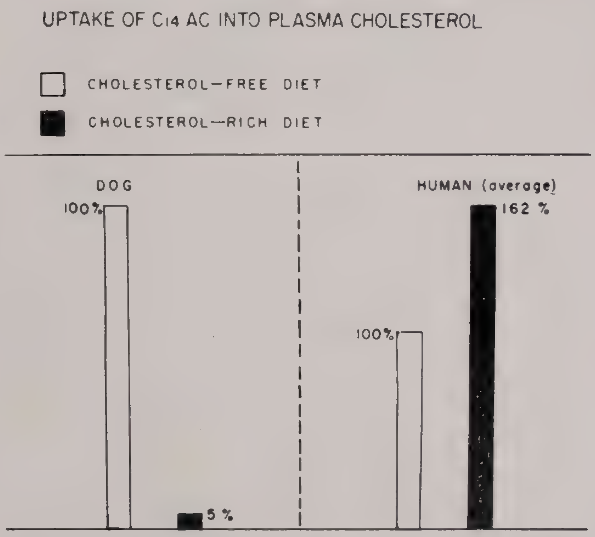

Fig. 2 — Effect of dietary cholesterol on appearance of C^{14} acetate-labeled endogenously synthesized cholesterol in plasma of dogs (on left) and man (on right). Clear bars represent amounts appearing when dog and eight subjects were on cholesterol-free diets; dark bars represent relative quantities appearing while dog and subjects were on cholesterol-rich diets. The 100% for cholesterol-free values was arbitrarily chosen as base line for this graph. Dog shows marked suppression (to 5%) of rate of appearance of labeled plasma cholesterol, whereas human subjects showed no compensatory suppression. Value of 162% for human subjects was probably over 100% because of shift in pathways for use of acetate pool caused by feeding of neutral fat with cholesterol.

cheese. This regimen excluded meat, egg yolks, cream, butter fat. All subjects were placed on this diet six weeks prior to the initiation of the studies.

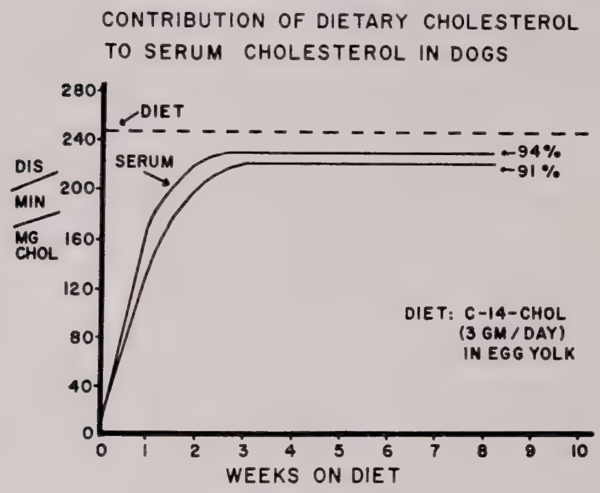

Fig. 3 — Graph presenting appearance of ring-labeled (4-C^{14}) dietary cholesterol in serum cholesterol of dogs. Radioactivity in disintegrations per min./mg. cholesterol is plotted on abscissa; time in weeks, on ordinate. Dotted line across top plots dietary radioactivity. Note that within three weeks the two dogs showed that 91 and 94% of their serum cholesterol contained the ring label, indicating that these percentages of serum cholesterol were derived from diet.

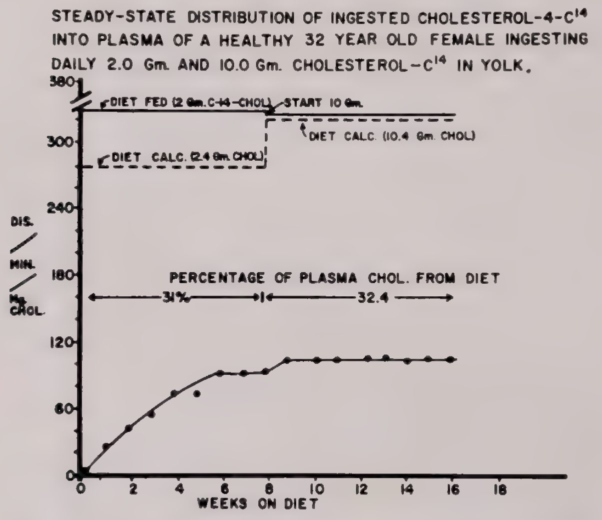

Fig. 4 — Graph similar to that of Figure 3, presenting rate of appearance of labeled (4-C^{14}) dietary cholesterol in serum of 32-year-old female subject. At about six weeks only 31% of serum cholesterol was derived from labeled dietary cholesterol. Interestingly, changing the diet from 2 gm. cholesterol/day to 10 gm./day resulted in only a minimal rise (to 32.4%) in per cent of serum cholesterol derived from labeled dietary cholesterol.

Baseline levels of normally occurring deuterium in urine and in serum cholesterol were obtained from all subjects. Subsequently, subjects were administered an oral priming dose of heavy water (D_2O) in concentrations high enough to raise the body water D_2O content to 0.5 moles % in excess of normal baseline D_2O. Doses averaged from 140 to 250 gm. D_2O. Thereafter, subjects received oral doses of D_2O daily, approximating 10% of their original priming dose to compensate for normal turnover of body water. All studies were run for a period of at least 40 to 50 days, and almost daily urine and serum samples were collected.

After completion of this initial study, subjects were allowed 7-10 months for the elimination of D_2O of body water, cholesterol and other endogenously synthesized deuterated organic molecules. Mass spectrometric analysis verified the return to baseline levels of the D_2O contents of body water and serum cholesterol.

The cholesterol-rich study was then instituted. This study provided an estimated daily dietary intake of 2.5 to 3.0 gm. cholesterol. The egg was the major cholesterol-carrying vehicle since an egg yolk contains approximately 250 mg. cholesterol. Again, urine and serum samples were collected almost daily for determination of deuterated body water levels and deuterium concentration in newly synthesized cholesterol.

The isolation, combustion and reduction of serum cholesterol were carried out in the following manner. Serum specimens were hydrolyzed with alcoholic KOH and extracted with petroleum ether and one portion of the extract analyzed for total serum cholesterol by the Abell-Kendall procedure[10] using a Lieberman color reaction (20-1, acetic anhydride-sulfuric acid). The remainder was converted to cholesterol digitonide. Pyridine was then added in order to split off the digitonide, and the cholesterol was extracted with acidified ether, purified and weighed. Specimens so isolated usually yielded from 2 to 4 mg. of pure cholesterol.

The isolated cholesterol was then combusted with copper oxide at 600°C. under high vacuum conditions in a sealed ampule of

Corning #1720 ignition glass. The ampule containing the CO_2 and H_2O of combustion was then placed in liquid nitrogen in order to condense and freeze the gases formed. Carbon dioxide was removed, and water driven over into a reduction ampule containing 0.5 gm. zinc. The reduction tube was then heated to 500° C. in order to reduce the H_2O and D_2O to H_2 and D_2 gas.

The deuterium assays were carried out in a Nier Model, RCA isotope ratio mass spectrometer at the Mayo Clinic. The mass spectrometer analyses consisted of measuring the mass 3 to mass 2 ratio. This ratio was then converted to heavy water concentration by reference to a calibration derived from five standards of various concentrations of D_2O and H_2O. The magnitude of error in the reduction and mass spectrometer analyses was of the order of ±4%.

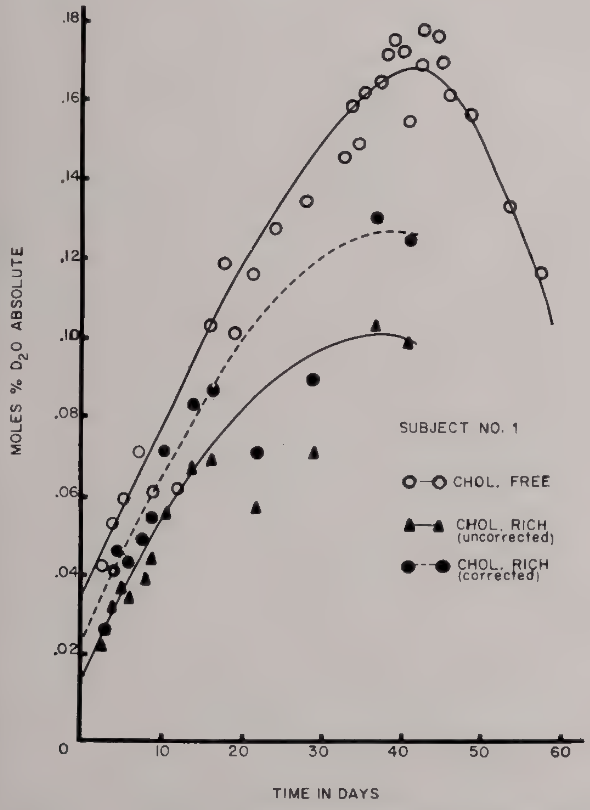

Fig. 5 — Serum cholesterol-deuterium enrichment curves of Subject 1 while on cholesterol-free (○——○) and cholesterol-rich diets (▲——▲). The middle curve is derived from corrected data of cholesterol-rich curve to correct for dilution of deutero-cholesterol by unlabeled dietary cholesterol. (See text for discussion of this correction.) Note again lack of effect of dietary cholesterol on rate of appearance of endogenously synthesized, labeled cholesterol.

Results and Discussion

The principal advantage of using deuterium is its negligible radioactivity which makes it possible to carry out long-term studies on humans without radiation as a hazard.

By enriching each subject's body water deuterium with the initial priming dose and daily doses of deuterium oxide, we were able to elevate and maintain the subject's labeled body water between 0.5 and 0.6 moles % D_2O. The labeling of newly synthesized cholesterol was adequate to provide meaningful data when D_2O enrichment was at 0.5 moles % D_2O in body water. Maximum enrichment of 0.1% D_2O in body water was shown to be experimentally unsatisfactory.

The maximal deutero-cholesterol concentrations were reached by 38-44 days in all eight studies. (Figure 5 is a graph of data from two studies on one subject.) These times are comparable to the study reported by London and Rittenberg in which maximum deutero-cholesterol-digitonide concentrations were reached on the 36th day.

Exogenous cholesterol feeding markedly

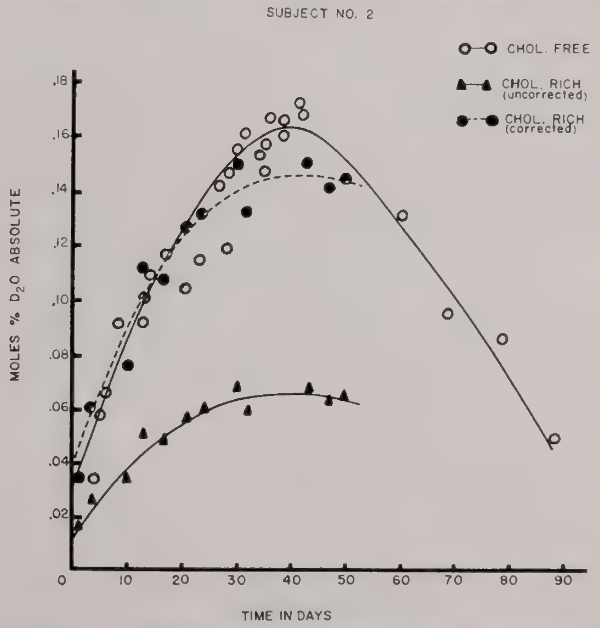

Fig. 6 — Serum cholesterol-deuterium enrichment curves of Subject 2. As discussed in the text, this subject's serum cholesterol increased 56% while he was on the cholesterol-rich study, resulting in a decreased maximum deuterium enrichment from over .16 to about .06. When corrections for exogenous dilution were made, the lower (cholesterol-rich) curve became very similar to the cholesterol-free curve.

increased the serum cholesterol levels. There was a marked increase in serum cholesterol of from 20 to 56 per cent. Since our studies showed simultaneous marked reduction of absolute deutero-cholesterol concentrations in the cholesterol-rich subjects, we felt this lower specific activity was due to the dilution effect of exogenous cholesterol on endogenously synthesized deutero-cholesterol. The most striking example was Subject 2 (Figure 6), whose mean serum cholesterol increased 56% while on the cholesterol-rich diet. His absolute deutero-cholesterol concentration, however, fell from 0.1640 moles % (cholesterol-low diet) to 0.0650 moles % D_2O on the cholesterol-rich diet. We corrected for the dilution of endogenously synthesized deutero-cholesterol by dietary cholesterol by determining the degree of dilution by exogenous cholesterol and increasing the moles % D_2O absolute by a corresponding factor. The effectiveness of this correction is demonstrated by the corrected curve obtained when the subject was on the cholesterol-rich diet. This effect was seen in all corrected curves.

By plotting the data on semi-log paper (in the manner of London and Rittenberg) one can obtain the half-life of serum cholesterol. This half-life is the time required to reach 50% of maximum deutero-cholesterol concentration. It also represents the time required for half the serum cholesterol molecules present in circulation to be synthesized. After one obtains the t ½, he can calculate the turnover rate of plasma endogenously synthesized cholesterol. This turnover is the mean survival time of serum cholesterol

TABLE 1

This table tabulates t 1/2 and $\bar{T}$ values for subject studied by London and Rittenberg and four of our subjects. Three subjects were studied while on both a cholesterol-free and a cholesterol-rich diet. Dietary effects on these values were negligible. A fifth subject receiving a much lower labeling dose of D_2O is not listed.

molecule and is related to the rate at which serum cholesterol molecules are synthesized. It is interesting to note the relatively unchanged t ½ and $\bar{T}$* in both cholesterol-free and cholesterol-rich groups (Table 1).

A compilation of the data on all subjects and comparison with the data of London and Rittenberg indicate that the absence of cholesterol or the presence of 2.5 to 3.0 gm. per day in the diet results in no significant change in the t ½ or $\bar{T}$ of plasma cholesterol.

The estimated quantities of newly synthesized cholesterol appearing in the plasma each day are also reasonably comparable to the quantity reported by London and Tittenberg (Table 2). Again, the essentially complete lack of an effect of dietary cholesterol on estimated daily plasma synthesis is striking.

Conclusion

The above studies and our earlier studies indicate an essential absence of a "feedback" mechanism in man for compensation for dietary cholesterol. These studies suggest a continuous unaltered rate of delivery of endogenous cholesterol to the plasma regardless of diet. They further suggest that absorbed dietary cholesterol is added to endogenous serum cholesterol, resulting in a net higher serum cholesterol concentration. There still remains another important, incompletely studied facet of cholesterol metabolism; this concerns the ability of man to alter his rate of conversion of cholesterol to bile acids and later fecal excretion of both bile acids and cholesterol to compensate for variable quantities of dietary cholesterol. Studies of this nature have been reported in dogs and six laboratories are actively studying this mechanism in man. Our laboratory has also begun studies in this area which, in our opinion, represents the only possible remaining mechanism of significance which man may have to compensate for absorbed dietary cholesterol.

---

*$\bar{T}$ = turnover rate.

The Patient's Duty — and the Doctor's

First, our duties to and about the Doctor; to call him in time, to trust him, to obey him, to be grateful to, and to pay him with our money and our hearts and our good word, if we have all these; if we have not the first, with twice as much of the others. Second, the Doctor's duties to us. He should be able and willing to cure us. That is what he is there for. He should be sincere, attentive, and tender to us, keeping his time and our secrets. We must tell him all we know about our ailments and their causes, and he must tell us all that is good for us to know, and no more.

— John Brown (1810-1882)

Primary Hyperparathyroidism

IT IS PARTICULARLY appropriate to review facets of calcium and parathyroid metabolism at a celebration honoring Dr. Gerald T. Evans because of his longstanding interest in mineral metabolism.

Hyperparathyroidism masquerades as many different diseases and can produce acute and sometimes rapidly fatal illness. The diagnosis depends entirely on precise clinical chemical data, but the recognition of the possibility of hyperparathyroidism depends on certain clues derived from clinical examination. There have been several articles in the recent literature describing the findings and course of hypercalcemic crisis due to hyperparathyroidism.[1-9] Experience with two patients with hypercalcemic crisis, another patient with pancreatitis, and a fourth with skeletal and renal symptoms will be presented because of certain instructive features.

Materials and Methods

Routine laboratory procedures were carried out. Alkaline phosphatase determinations were made using the King-Armstrong method.[10] Serum and urine calcium and magnesium determinations were made using the Zeiss flame photometer with a double monochromator,[11] and calcium determinations were also made using the EDTA calcein method.[12] The mean of serum calcium values in normals by the flame spectrophotometer is 10.2 ± .22 mg. per cent, and by the EDTA calcein method 9.66 ± .41 mg. per cent. The mean value of serum magnesium in normals is 1.77 ± .12 mEq./L. Phosphorus was determined by the Fiske and Subbarow method,[13] and creatinine and blood urea nitrogen values were determined using a Technicon auto-analyzer. Urinary hydroxyproline was determined by the Prockop and Udenfriend method.[14]

Case 1

A 47-year-old white married woman was admitted to the hospital on June 10, 1963. She had been profoundly weak for ten days. Seven days before admission she had fallen in the bathroom and sustained a bruise above her right eye. She was nauseated and vomited frequently. Her bowels had not moved for the preceding five days, but they had moved three times the day before admission. Twelve hours before admission she had cramps as well as constant pains in the calf muscles of both legs. In spite of vomiting she was able to drink water and carbonated beverages; so her urine output had not decreased. She had not felt well for months but had been able to take care of household duties. She was so lethargic that it was difficult to get details of history, and her mental status rapidly deteriorated.

Causing Hypercalcemic Crisis and Acute Pancreatitis

EDMUND B. FLINK, M.D.*
PAUL C. DESPER, M.D.**
JOHN E. JONES, M.D.†
Morgantown, West Virginia

Examination

On examination her temperature was 37° C., her pulse rate 70, her blood pressure 140/90, and her weight 49.2 kg. She was very lethargic and so weak she could not stand without help. Her tongue and lips were dry and her skin turgor was poor. The optic discs were normal, the retinal arteries were of normal caliber, and there were no retinal hemorrhages. A small right periorbital hematoma was noted. The tympanic membranes of both ears were normal, and the nostrils were patent and free of exudate. The gag reflex was present. The lymph nodes were not enlarged. The neck was supple. The lungs were resonant throughout and breath sounds were normal. The heart tones were normal, and the rhythm was regular. Masses interpreted as feces were palpated in both right and left lower abdominal quadrants. The spleen and liver were not palpated. Pelvic examination revealed normal external and internal genitalia. Touch and superficial pain senses were intact. Biceps, triceps, quadriceps, and Achilles reflexes were symmetrical and brisk. Quadriceps and iliopsoas muscle weakness was marked.

Laboratory Findings

The hemoglobin was 14.8 and 15.0 grams per cent; the leukocyte count ranged from 21,400 to 24,800/cu.

mm. with 92 per cent neutrophils, 4 per cent lymphocytes and 4 per cent monocytes. The blood glucose was 108 mg. per cent. Urinary excretion of hydroxyproline was measured on a specimen of urine collected for three hours immediately before surgery. The output was 33.3 mg. for three hours. If this value is extrapolated to a whole day, the excretion would have been 268 mg/24 hours. Cerebrospinal fluid protein was 61 mg. per cent. Serial laboratory data are recorded in Table 1 and electrocardiograms in Figure 1.

Progress

Her physical and mental status deteriorated rapidly. The weakness and other symptoms were ascribed to dehydration and hypokalemia. Although transient improvement lasting for about twelve hours resulted from hydration and potassium administration, on the day after admission she became more ill, was more lethargic and became confused and disoriented. During the period of fifty hours before operation, she received a total of 10.5 liters of fluid with 710 mEq. of sodium chloride, 300 mEq. of potassium chloride and 48 mEq. of magnesium sulfate. Her blood pressure fell to 90/70. She developed various cardiac arrhythmias: atrial flutter, premature contractions and nodal rhythm. On June 12 her serum calcium was found to be 24 mg. per cent, rising later that day to a high of 28.4 mg. per cent. A diagnosis of hypercalcemic crisis due, most likely, to hyperparathyroidism was made.

Treatment

She was treated with calcium-disodium edatate, hydrocortisone, and metaraminol for a three-hour period and then an exploration of the neck was carried out. A 9.7 gram parathyroid adenoma was removed from the region of lower pole of the left lobe of the thyroid. She did not regain consciousness after the operation; but she lived for about 20 hours. It became increasingly difficult to maintain her blood pressure. Her urine output rapidly decreased and total output was only 96 ml. after the operation. Because of a rapidly rising potassium and failure of the serum calcium to fall, peritoneal dialysis was instituted at 2:00 p.m. on June 13. However, her condition became progressively worse, her blood pressure could not be maintained with vasopressor agents and she died at 4:10 p.m.

Autopsy Findings

An autopsy was performed. The main features of this examination were: atelectasis of lungs with pulmonary edema, nephrocalcinosis, acute and chronic pyelonephritis and acute cystitis, metastatic myocardial calcification, eosinophil hyperplasia of pituitary, satellitosis,* chromatolysis, and myelin sheath degeneration of the brain.

Case 2

A sixty-four-year-old white married woman was admitted for the first time on April 28, 1964, for evaluation of chronic constipation, weakness and lethargy, heart trouble, persistent nausea and vomiting of two weeks' duration, and "nervousness." She gave a history of Bright's disease at age twenty-four, and she had had kidney difficulties since that time. She had been treated elsewhere during the preceding year for chronic cystitis. Her blood urea nitrogen was known to have been elevated for a minimum of one year before referral. There was no history of renal lithiasis or hematuria. She had complained of pain in the pelvis. A diagnosis of myocardial infarction had been made six to seven years earlier. She had been hospitalized elsewhere ten days

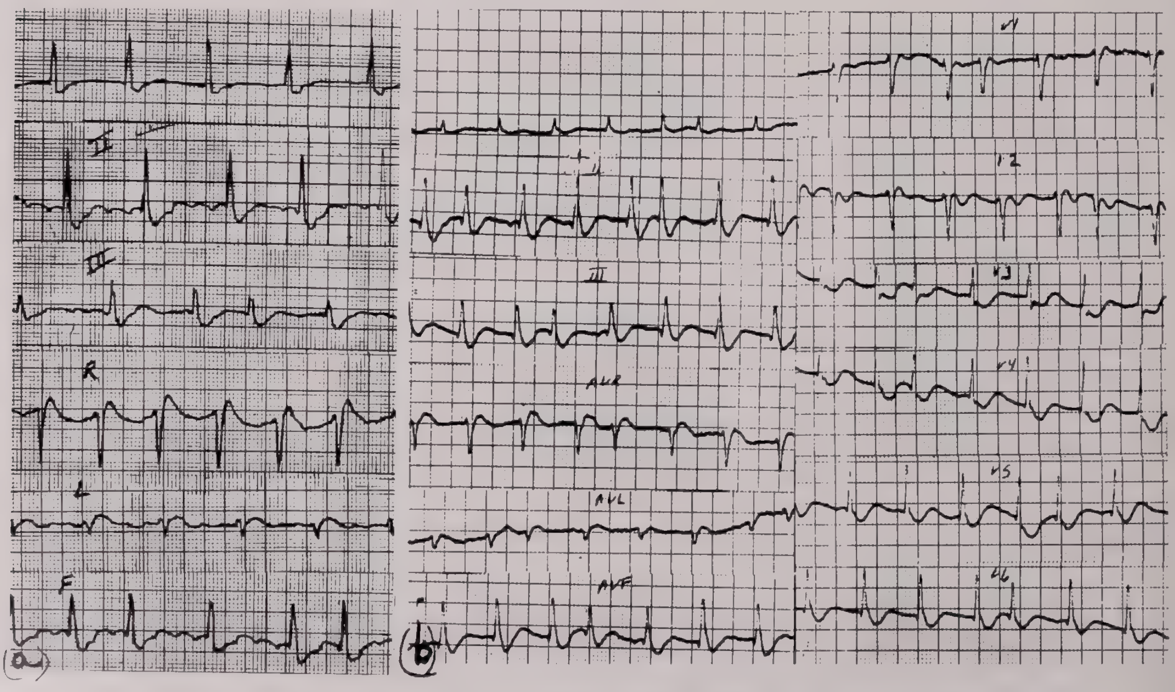

Fig. 1 — (a) Tracing taken 6/11/63 showing atrial flutter. (b) Tracing taken 6/12/63 showing nodal rhythm and bizarre ST intervals and T waves with short QT intervals.

---

*See Test Your Word Score Page 779.

before referral and treated with diuretics because of peripheral edema, ascites, and paroxysmal nocturnal dyspnea with resultant loss of seventeen pounds of weight. Because of "anemia" she received a transfusion of two units of whole blood during that hospitalization. Medications at the time of admission included pentaerythritol tetranitrate, nitroglycerin, chlorothiazide, digitoxin (0.2 mg. daily), pentobarbital sodium, carbromal, and trimethobenzamide. Her family said that she had always been a demanding, complaining woman, and they suggested that she might have had hallucinations in the recent past. She had had a cholecystectomy at age 49.

Examination

Physical examination revealed a blood pressure of 128/80, a pulse rate of 80 per minute, respirations of 22 per minute and weight 44.6 kg. She was alert and oriented. There was bilateral corneal "band" keratopathy.* A diffuse non-nodular anterior neck mass rose on swallowing and extended substernally. The heart was enlarged to the left. The cervical veins were flat and the lungs were clear. The bowel sounds were active and there was minimal abdominal distention. There was marked generalized muscular weakness and mild dehydration.

Laboratory Findings

The urinalysis showed 1+ proteinuria and hyposthenuria with specific gravities of 1.004 to 1.010. The hemoglobin was 13.2 gm.%, hematocrit 41%. The leukocyte count was 12,600 with 86 per cent neutrophils, 13 per cent lymphocytes, 1 per cent monocytes. The sedimentation velocity was 24 mm./hour (Westergren). The VDRL was nonreactive and the BUN 63 mg. per cent with a creatinine of 3.2 mg. per cent. Serum bilirubin and bromsulfalein tests were normal. An arterial pH was 7.41 with pCO_2 of 37.5 mm. Hg. Urinary calcium excretion on the day before surgery was 148 mg./24 hours. Urinary excretion of hydroxyproline was 125 mg./24 hours. The results of serial tests are recorded in Table 2. A skeletal survey revealed a characteristic granular appearance in the skull and absent lamina dura. The pineal gland was calcified and showed no displacement. There was generalized demineralization with coarse bony texture and extensive periarticular calcification of the wrists, shoulders, hips and knees. The meniscus in the knees and the veins of the lateral aspect of the right lower leg were calcified. The Fallopian tubes appeared to be calcified. There was characteristic subperiosteal bone absorption of the proximal phalanx of the left index and middle finger. An electrocardiogram showed a markedly prolonged PR interval, intraventricular conduction defect and nonspecific T wave changes. The atrial rate was variable (Figure 2). An I^{131} uptake was 8 per cent at 24 hours. A thyroid scan, while technically imperfect due to the low uptake, indicated diffuse uptake over the left side of the gland but definitely less uptake on the right. A diagnosis of primary hyperparathyroidism was made.

Treatment

She was treated with intravenous fluids, potassium and sodium salts (primarily as the phosphate and lactate respectively). Digitalis was discontinued. Because she was well oriented and was improving with replacement therapy, her surgery was delayed until the third hospital day when her serum electrolytes were more nearly normal. At surgery a 6 cm. by 3 cm., 25 gram adenoma was removed from the right thyroid region. Microscopic section showed parathyroid adenoma of chief cell type. Her serum cal-

cium remained elevated for eleven days postoperatively. Eighteen days postoperatively her serum calcium fell to 8.3 mg. per cent and she developed mild paresthesias. On the twentieth postoperative day her serum calcium was 7.1 mg. per cent, phosphorus 6.0 mg. per cent, and she was given small doses of Calciferol with subsequent maintenance of her serum calcium in the 8 to 9 mg. per cent range.

Progress

Her BUN progressively fell to 32 mg. per cent by the tenth postoperative day. Repeat electrocardiograms revealed gradual diminution of the PR interval. Because of cardiomegaly and a past history of congestive heart failure, she was again given digitoxin. Desiccated thyroid was started. Aside from one period of hallucinations and paranoia shortly after surgery, her postoperative course was uncomplicated.

Outpatient follow-up visits have shown the need of diuretics to control fluid retention. Calciferol has been stopped and her serum calcium remains in normal range. Mild constipation is now easily controlled with occasional cathartics.

Case 3

A twenty-five-year-old white married woman was admitted July 8, 1963, to the hospital for evaluation of hypercalcemia and a history of recurrent pancreatitis. She was working regularly as a nurse until the time of her admission. She had enjoyed good health all her life until age twenty-one when she developed preeclampsia in the seventh month of her first pregnancy, terminating with a still birth one month later. She was again well, but in the following two years she developed pneumonia which was successfully treated with chloramphenicol. Subsequently, she had a bout of acute pancreatitis. An upper gastrointestinal study and a cholecystogram following the acute illness were normal. A second pregnancy was terminated by Cesarean section near term because of abruptio placenta. A viable infant was delivered. He had no convulsions during infancy. Ten months before her admission she had a second bout of acute pancreatitis. Following this, she returned to her usual state of health. At the time of her admission she had no specific complaints but was admitted because an elevated serum calcium was found in an effort to explain her episodes of pancreatitis. On specific questioning she admitted having decreased energy for the preceding two to three years and polydipsia and polyuria for as long as two years. Frequent dull occipital headaches had been present for the preceding two months. She denied visual disturbances. She had never had renal or urinary tract symptoms. There had been no nausea, vomiting, diarrhea, or constipation. Her two male siblings and her parents were in good health.

Examination

On physical examination she was a healthy appearing young woman, 170.5 centimeters tall and weighing 64.4 kilograms. The vital signs and the physical examination were entirely normal. No neck masses were palpated.

Laboratory Findings

A urinalysis showed a specific gravity of 1.015 and a faint trace of albumin; red blood cells were present, and there were fairly numerous granular casts. The hemoglobin was 13.6 gm. per cent with a 41 per cent hematocrit. There were 5,500 leukocytes with 54 per cent neutrophils, 42 per cent lymphocytes, 1 per cent eosinophils and 3 per cent basophils. Wintrobe sedimentation rate was 6 mm. in one hour. Blood urea nitrogen was 18.5 mg. per cent. Multiple serum calcium determinations ranged between 14.2 mg. per cent and 16.0 mg. per cent, and phosphorus from 1.6 to 2.5 mg. per cent. The total serum protein was 7.6 gm. per cent with 4.5 gm. per cent albumin, and 3.1 gm. per cent globulin. Alkaline phosphatase was 12.3 King Armstrong units. Sodium, potassium, chloride and CO_2 determinations were all normal. Plasma magnesium ranged between 1.55 and

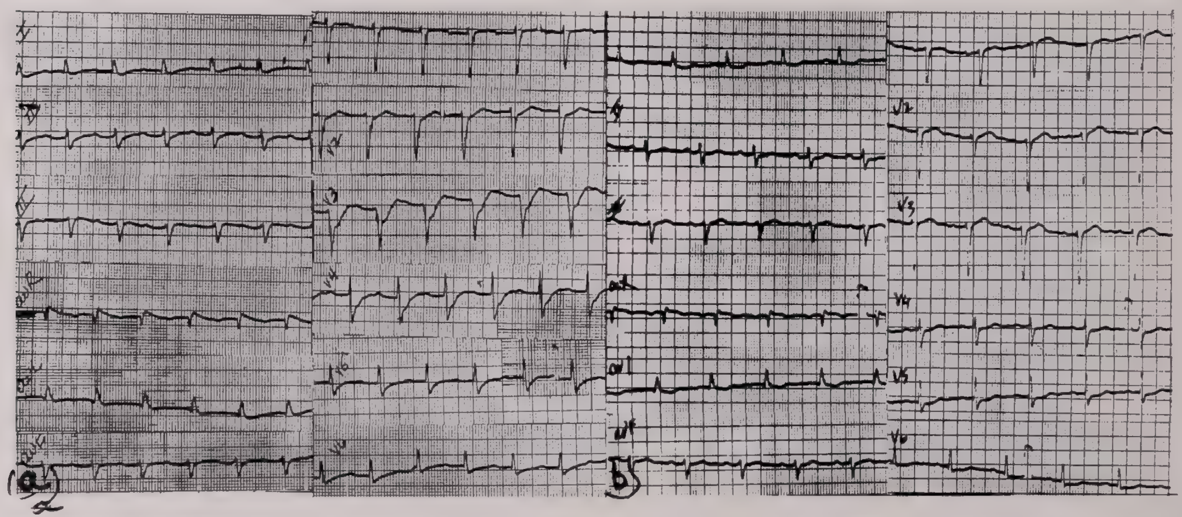

Fig. 2 — (a) Tracing taken 4/30/64 showing prolonged PR interval and bizarre ST segments. (b) Tracing taken on 5/11/64. PR now normal and T and ST changes have disappeared.

2.0 mEq/L. Urinary calcium excretion ranged from 594 to 712 mg./day on three consecutive days. Additional laboratory data are recorded in Table 3. Radiographic examination of the chest was normal and an esophagogram showed no displacement of the esophagus. Films of the hands were normal. An electrocardiogram was normal. The phosphorus excretion pattern was not altered by calcium infusion, (positive Goldsmith test).[15] A diagnosis of primary hyperparathyroidism was made and confirmed at surgery.

Treatment and Progress

A 1.2 x 1.2 cm. adenoma was excised from the left side of the neck, adjacent to the inferior pole of the left lobe of the thyroid gland. Histologic sections showed it to be a chief cell adenoma. Her postoperative course was smooth. The serum calcium reached normal levels on the third postoperative day. There was no hypocalcemia following surgery. She has returned to work, and serum calcium levels six and twelve months after surgery have been normal. She delivered a normal child after an essentially uneventful pregnancy just thirteen months after surgery. She is now in her fourteenth postoperative month and continues to be in good health.

Case 4

A 62-year-old white married woman was referred to this hospital on February 3, 1964, with a diagnosis of probable hyperparathyroidism. On admission she complained of pain in her bones and nervousness.

Because of pain in her back and extremities a diagnosis of rheumatoid arthritis had been made in 1951. She had episodes of acute renal colic without recovery of stones in 1954 and again in 1955. In 1958 she began having recurrent urinary tract infections. During this period she passed multiple urinary calculi and one year before admission a ureteral stone was removed surgically. About that time an intravenous urogram had failed to visualize the kidneys. In the last six months she had had increasing pain in her back and extremities, but there was no associated joint swelling. She had been treated for episodic diarrhea and on admission she was being treated for glaucoma. She had a right salpingo-oophorectomy at age 28 and cholecystectomy at age 38. There was no history of peptic ulcer, pancreatitis, or polydipsia. She had muscle weakness and intermittent headaches on the right side.

Because of persistent bone pain and the history of recurrent urinary tract disease, her physician measured her serum calcium and found it to be elevated.

Examination

On admission she was alert, ambulatory, and oriented. Her blood pressure was 126/88 and her pulse was regular, varying between 70 and 88 per minute. She weighed 58.8 kg. Examination of the eyes showed normal pupils and fundi, but cupping of the temporal margin of the optic disc was noted bilaterally. Keratopathy or cataracts were not detected. She was edentulous. The thyroid gland was normal except for a single nodule in the left lobe. There was dorsal kyphoscoliosis, the chest was clear to auscultation and percussion, and there was tenderness to palpation over the left anterior thorax. Examination of the heart was normal except for a Grade I systolic murmur at the apex. There were well healed abdominal surgical scars. Pelvic examination was normal. The extremities were normal without any evidence of joint deformities.

Laboratory Findings

Laboratory studies included a hemoglobin of 11.0 gm. per cent, an erythrocyte count of 4.5 million, an hematocrit of 34.5 per cent, and a leucocyte count of 8,800/cu. mm. with 59 per cent neutrophils, 37 per cent lymphocytes, 4 per cent monocytes. The Wintrobe sedimentation rate was 20 mm. in one hour. The specific gravity of urine was 1.008, the pH 7.0; there were 2-3 WBCs per high power field and 1-2 casts/low power field. There was no proteinuria or glyco-

TABLE 3

suria. The BUN was 17 mg. per cent. The sodium, potassium, chloride, and carbon dioxide were normal. The serum creatinine was 1.1 mg. per cent and an alkaline phosphatase was 10.1 K.A. units. There were 6.9 gm. per cent total serum proteins with 3.7 gm. per cent albumin and 3.2 gm. per cent globulin. Serum calcium determinations ranged from 14.8 to 16.8 mg. per cent (Zeiss) and phosphorus from 1.7 to 1.88 mg. per cent. A calcium infusion did not change the phosphorus excretion (positive Goldsmith test).[15]

A radiographic survey of the skeleton showed extensive generalized demineralization compatible with hyperparathyroidism. An electrocardiogram was normal. A diagnosis of primary hyperparathyroidism was made and confirmed at the time of surgery.

Treatment and Progress

A 3.0 by 1.0 by 1.0 centimeter nodule weighing 3.0 gm. was removed from an area adjacent to the inferior pole of the left lobe of the thyroid. Histologically this was a parathyroid adenoma composed of an admixture of chief cells and clear cells.

Her surgery and postoperative course were uncomplicated except for a drop in hemoglobin to 8.4 gm. per cent by the eighth postoperative day. There was no excessive blood loss at surgery nor was any other source of bleeding found. By 23 days after surgery the hemoglobin had risen to 10.0 gm. per cent.

She was seen two months after surgery, at which time she was feeling well. She had had no symptoms suggestive of hypocalcemia. Subsequent to that time she has failed to return to clinic for further evaluation.

Discussion

Parathyroid hormone has multiple actions.[16] Some of the activity undoubtedly is the result of shifts in equilibrium reactions. Parathyroid hormone increases the absorption of calcium from the small intestine; for this action Vitamin D is also necessary. At the cellular level it: (1) inhibits oxidative phosphorylation of isolated liver mitrochondria, (2) increases the aerobic lactate production of bone slices in vitro, (3) increases the turnover of various organic phosphate esters and the phosphoproteins of the kidney, (4) increases the P^{32} and Ca^{45} transport in isolated loops of intestine, and (5) inhibits uptake of radioactive glycine C^{14} by bone grown in tissue culture. It increases citrate, phosphate, potassium and sodium excretion and decreases hydrogen ion excretion by the kidney. It increases renal tubular reabsorption of calcium; the paradoxical* increased excretion of calcium in hyperparathyroidism is the result of increase in total and ultrafilterable serum calcium. Therefore the increase in calcium of glomerular fluid results in a net increased excretion of calcium. During in-vitro incubation of bone preparations, the hormone causes disappearance of typical osteoblasts, the formation of multinuclear osteoclasts, the dissolution of bone matrix, and changes in epiphyseal cartilage and connective tissue pattern. Parathyroid hormone mobilizes calcium from bone. It has an effect on ground substance of bone and on the production of citric acid and lactic acid by bone cells.

Calcium Intoxication from Parathyroid Hormone

There have been at least 29 deaths due to acute calcium intoxication (1, 5, 9, present case). The course of illness has been characteristic, with fulminating progress beginning with profound muscular weakness and progressing to hypotension and death in the course of seven to fourteen days unless it is recognized and treated. Although a few instances have occurred in childhood and early adult life, the majority of instances have occurred after the age of 40. The most important symptoms are muscular weakness, nausea and vomiting, weight loss, lethargy, confusion and other evidence of delirium, abdominal pain, polyuria, polydipsia, constipation and coma. Bone pain and renal colic also occur frequently but are not constant or prominent symptoms in the majority. Obviously, any symptom which acts as a clue is worthy of note. The emphasis rests on muscular, gastrointestinal and mental symptoms in hypercalcemic crisis.

Patient 1 demonstrated most of the features of acute calcium intoxication. Her illness was recognized late in its course. Shock was irreversible in the postoperative period.

Patients 1 and 2 both had leukocytosis. In Patient 1 the very high leukocyte count resulted in a great deal of effort to find an infectious process. Leukocytosis of this degree has been reported.[3,7] This finding could lead to an erroneous diagnosis or at least to fruitless diagnostic efforts. The mildly elevated spinal fluid protein is indicative of central nervous system irritation and has been reported before.[1] Again this laboratory finding can be misleading in a patient with profound central nervous system symptoms suggesting an acute neurosurgical problem.

Palpable Mass

The finding of a neck mass has been reported in 42 per cent of cases.[1] In Patient 2 a mass interpreted as a goiter was palpated. She had symmetrical enlargement in the region of her thyroid gland. An I^{131} scintogram of her neck revealed the concentration of iodine predominantly on the left side. One possibility, therefore, was that the mass on the side opposite that concentrating I^{131} was actually a parathyroid adenoma. This proved to be true, but this possibility was only casually hinted at before identifying the adenoma. An I^{131} thyroid scintogram could prove to be useful in identifying adenomas in the thyroid gland, impinging on it or displacing it just as esophagograms and arteriograms have proved to be useful.

Electrocardiographic Findings

Electrocardiographic changes in Figures 1 and 2 are typical of those previously published.[4,5,17,18] The changes in electrocardiograms in Figure 2 are less severe than those in Figure 1. The changes disappear after calcium returns to normal. The tracings suggest hypokalemia because of the bizarre, sagging ST segments; but the QT interval in hypercalcemia is very short, and the PR interval is prolonged. Electrocardiographic changes in hyperparathyroidism were first suggested in 1932 by Ballin[19] and were more clearly defined in 1936 by Kellog and Kerr.[20] In 1956 Bradlow and Segel[4] published a definitive account of electrocardiographic changes. The most characteristic of these changes are prolonged PR interval, shortened QT interval, sagging of the ST takeoff and shortening and straightening of the ST interval so that QaT interval (Q to apex of T) is particularly short.[17] Patients 1 and 2 both exhibited rather striking changes. The arrhythmias which occurred in Patient 1 are potentially dangerous, and some patients with severe hypercalcemia undoubtedly die as a result of serious rhythm disturbances. Although electrocardiographic changes such as prolonged PR and shortened QT intervals are often described, relatively few reproductions of electrocardiograms have been published.[4,5,17,18] The changes are striking and worthy of reproducing, since some of them are difficult to describe. Figures 1 and 2 may serve as a clue for recognition of other cases of calcium intoxication. The similarity of findings and reversion toward normal as noted in Figure 2 are convincing evidence of the diagnostic value of these changes. Patients 3 and 4 had normal electrocardiograms.

Electrolyte Disturbances

Potassium disturbances have been noted recently. Three of four patients reported by Lemann and Donatelli[1] had hypokalemia. Both Patients 1 and 2 had hypokalemia. Patient 2 had been treated with chlorothiazide, but Patient 1 had received no medications. Potassium wastage by the kidney could be due entirely to renal damage by hypercalcemia as suggested by studies on Vitamin D intoxication.[21] Poor food intake certainly contributed to a net loss. Parathyroid hormone increases potassium excretion by the kidney, so this action undoubtedly could contribute to potassium depletion.[16]

Magnesium depletion has been documented in patients with hyperparathyroidism by demonstration of a significantly positive magnesium balance after parathyroidectomy[22] and by recognition of magnesopenia following parathyroidectomy with attendant nervous and mental symptoms.[23,24] The delirium following parathyroidectomy recently reported[25] was not due to hypocalcemia, but could have been due to magnesium depletion. Delirium following parathyroidectomy is fairly common and magnesium depletion is an important cause. A balance study of Patient 2 revealed a distinctly positive magnesium balance during the first twelve postoperative days. She developed mild delirium with paranoid ideas on the fourth postoperative day. Her serum magnesium dropped to a low of 1.15 mEq./L. on the second day, after which time she received small doses of magnesium on days 3, 4, 5, 6, 8, and 9. A positive balance of 35.8 mEq. or 0.9 mEq./Kg. magnesium occurred in 12 days.

Differential Diagnosis

The differential diagnosis of hypercalcemia includes sarcoidosis; vitamin D intoxication; lymphoma; Hodgkin's disease; multiple myeloma; metastatic cancer to bone; carcinoma of lung, kidney, ovary, or pancreas without skeletal metastasis; and skeletal immobilization following fracture of large bones, especially in Paget's disease and in adolescents. In instances of hypercalcemia without serious systemic symptoms it is worthwhile to administer cortisone (or related steroid) for a week and follow the serum calcium level. In most patients with hypercalcemia due to causes other than hyperparathyroidism, cortisone will lower calcium to or toward normal. Occasionally patients with hyperparathyroidism also respond to cortisone with lowering of calcium to normal.[26,27] Hypercalcemic crisis is so serious that delay for observation of cortisone effect is not warranted. Emergency surgery is indicated, unless it already has been clearly established that the hypercalcemia is due to another cause.

Medical Management

The administration of calcium disodium edatate or citrate has theoretical value. Both were used in the first patient. Calcium disodium edatate has been found to be nephrotoxic. Neither citrate nor calcium disodium edatate had any appreciable effect. Albright, Bauer, Chaflin and Cockrill[28] showed that a high phosphate and low calcium intake lowered serum calcium in hyperparathyroidism. However, such a program should not be used as a long-term treatment because it could enhance metastatic calcification. A low calcium (100 mg/d) and high phosphate diet was used by Bradlow and Segel[4] for ten days, with lowering of calcium and BUN and remarkable improvement in one patient. Dent[26] has used 10 to 15 grams of sodium phosphate orally daily with distinct lowering of calcium levels. A total of 230 mEq. of potassium phosphate was administered in two days to Patient 2 preoperatively. During the operation and postoperatively, sodium lactate was infused because of the demonstration that lactate enhances excretion of divalent cations.[29] Sodium sulfate has been recommended because sulfate ion enhances divalent cation excretion.[30]

Sequellae

Pancreatitis is an important associated illness and one which should suggest hyperparathyroidism, particularly in patients who have no apparent illness such as cholelithiasis or alcoholism. Up to 1962 Mixter, Keynes, and Cope[31] were able to collect 62 cases of hyperparathyroidism and pancreatitis. Pancreatitis may complicate acute parathyroid crisis.[1,7] Ten of 380 patients at the Mayo clinic had pancreatitis.[32] The occurrence of two bouts of pancreatitis in Patient 3 was the clue which led to the diagnosis of hyperparathyroidism. In acute pancreatitis the serum calcium may fall to low levels and tetany occur. During an episode of acute pancreatitis, therefore, a normal or even low serum calcium does not exclude hyperparathyroidism. It is important to determine the serum calcium in a symptom-free interval in order to avoid values lowered transiently by the acute pancreatitis. The symptoms of pancreatitis have been corrected for more than a year in Patient 3. Amelioration of symptoms of pancreatitis after correction of hyperparathyroidism can be anticipated.[31] Pancreatitis has occurred in several patients with familial hyperparathyroidism.[33]

Neonatal hypocalcemia with infant convulsions has been reported occasionally in children born of mothers with hyperparathyroidism,[34] but this was not a problem in the child of Patient 3. Although it cannot be stated categorically that the fetal death and premature separation of the placenta in the three years before operation in Patient 3 were due to hyperparathyroidism, the successful and uneventful pregnancy since parathyroidectomy strongly suggests this relationship. Reports of pregnancies complicated by hyperparathyroidism indicate that fetal death and the other complications may occur with greater frequency than expected.[34] Parathyroid hormone has an effect on ground substance and could cause increased ease of placental separation. An interesting case has recently been reported by Preston and Adicoff[35] of avulsion of the patellar and triceps brachialis tendons in a patient with hyperparathyroidism. This can also be ascribed to the effect of parathyroid hormone on ground substance and connective tissue in general.[36] The greatly increased hydroxyproline excretion in hyperparathyroidism has been confirmed in two of our patients. Many factors influence hydroxyproline excretion. Excretion is increased by growth hormone, parathyroid hormone, and during periods of rapid growth during puberty.[9,37,38,39] Calcium infusion in patients with hyperparathyroidism[39] and in a patient with hypoparathyroidism[37] produced no fall in hydroxyproline excretion. However, calcium infusion in normal persons produces a fall in hydroxyproline excretion.[37] Contrary to the report of Klein, Albertson, and Curtiss,[7] Patient 1 had a normal level of alkaline phosphatase but, nevertheless, had a very high excretion of hydroxyproline. The second patient did have a modest increase of alkaline phosphatase and also an elevated hydroxyproline excretion.

In the Mayo Clinic experience, Keating reports that 64 per cent of their 380 patients had presenting symptoms indicative of renal calcinosis, and that another 12 per cent had associated symptoms referrable to urinary calcinosis. The history of renal stones and renal infections as well as bone pain in Patient 4, therefore, is the usual or expected one. Keating points out that hypercalcemia may be trivial in some instances. Fifty-two patients proven to have hyperparathyroidism at operation had one or more calcium values within the normal range preoperatively. The serum phosphorus was less reliable than the calcium. Goldsmith[15] has reviewed experience with a calcium infusion test which he devised. Infusion of 180 mg. of calcium interrupts the normally occurring rise in phosphate excretion during the morning hours, but not in hyperparathyroidism. He reports twenty patients with a positive test, all of whom proved to have hyperparathyroidism, although some had normal serum calcium and phosphorus values. As hypercalcemia was marked in all our patients, phosphorus clearance tests were not really necessary. The Goldsmith test was positive in the two patients so tested.

Multiple endocrine adenomas of the pituitary, the parathyroid, and the pancreatic islet cells occur in the same patient and may occur in families.[32,33] Hyperparathyroidism may occur with the Zollinger Ellison syndrome.[32] One should be alert to the possibility of the development of an adenoma of one or the other of the three glands in a patient who is being treated or has been treated for an adenoma of one of these glands.[40]

Summary

During a one-year period the diagnosis of hyperparathyroidism was confirmed in four patients.

One patient died of hypercalcemia crisis. She had a fulminant course of illness. Another patient had similar symptoms but was less severely ill and recovered following parathyroidectomy. Both patients had nausea and vomiting, mental symptoms, constipation, profound weakness, hypokalemia, azotemia, leukocytosis, and characteristic electrocardiographic changes. The first patient developed delirium and finally became comatose. Suggestions are made for the management of crises.

The third patient had several attacks of acute pancreatitis and had had serious complications of pregnancy on two occasions (fetal death once and abruptio placentae once). She also had pronounced weakness, thirst, and polyuria. A fourth patient had a more characteristic course with recurrent renal colic and bone pain. She also was very weak.

A drop in serum magnesium levels after surgery occurred in three patients and one had a low level initially. Postoperatively a magnesium balance was measured in this patient and was positive.

Addendum

Since submission of the manuscript, a paper entitled "Inorganic Phosphate Treatment of Hypercalcemia of Diverse Etiologies" (NEW ENGLAND JOURNAL MEDICINE 274:1, 1966 by R. S. Goldsmith and S. H. Ingbar) defines a practical and effective procedure for treating hypercalcemic crisis.

MILK DRINKER'S SYNDROME (Burnett's Syndrome)

During excessive milk alkali therapy for peptic ulcer, hypercalcemia, alkalosis and transient renal insufficiency with azotemia may develop to cause this syndrome. The excessive use of milk, cream and calcium carbonate may in some individuals cause symptoms of headaches, nausea, vomiting, anorexia, dizziness, irritability, mental confusion, depression, ataxia, stupor and toxic psychosis in progressive order. Serum phosphorus and alkaline phosphatase levels are normal and absence of skeletal demineralization aids in differentiating this from primary hyperparathyroidism.

Structure and Function of the Lung

RICHARD V. EBERT, M.D.*
Little Rock, Arkansas

PULMONARY EMPHYSEMA is characterized by destruction of the normal architecture of the lung. Alveolar septa are lost, and the normal air spaces are replaced by larger air-containing structures of variable size. Attention has focused on the normal architecture of the lung and its relation to function. Structure and function are of necessity closely related, and one cannot be understood without knowledge of the other.

The size of the terminal air spaces is of particular importance in the functioning of the lung. D'Arcy Thompson[1] in his excellent discussion of the relationship between structure and physical forces has emphasized the importance of magnitude. Taking L as the linear dimension of any object, and assuming that the size of the object varies but not the form, then the surface area will be proportional to the square of L, and the volume will vary with the cube of L. Thus each time L is doubled, there occurs a fourfold increase in area but an eightfold increase in volume. As a result, and because weight is a function of volume, large solid objects have a small surface area relative to their mass, and small objects a relatively large surface area. The force of gravity and the strength of structure and materials limit the size of large animals and plants. Surface tension becomes an important force in the functioning of small organisms. The power of surface forces can be observed on any pleasant summer day by examining the behavior of insects on the surface of a quiet pond.

The Surface Area of the Lung

The Diffusing Capacity

The function of the lung is to supply oxygen and to remove carbon dioxide from the blood. If the human lung were a simple sac the surface area would be small and the diffusing capacity extremely low. The diffusing capacity is usually measured by determining the uptake of carbon monoxide by the lung and is expressed as the volume of a gas which is transferred in a given period of time from alveolar air to capillary blood divided by the gradient of gas tension between the alveolar air and the blood.[2] The diffusing capacity is dependent on the surface area of the lung as well as on the thickness of the membrane separating the alveolar air and capillaries. If the diffusing capacity for oxygen is abnormally low, the hemoglobin of the pulmonary arterial blood will not be saturated with oxygen during its passage through the pulmonary capillaries.

---

*From the Department of Medicine, University of Arkansas Medical Center, Little Rock, Arkansas.

The Surface Area

The human lung is, of course, not a simple sac but is divided into small air spaces (alveoli) by innumerable septa, which greatly increase the surface area available for diffusion of gases. They are richly supplied with capillaries to permit this exchange of gas. Recent studies by Weibel[3] have shown the surface area of the adult human lung to measure approximately 75 square meters. The average diameter of the alveoli is 275 micra. If the lungs are destroyed by disease or if the septa are lost as in pulmonary emphysema the diffusing capacity of the lung decreases.

The division of the lung into innumerable small spaces with the consequent high ratio of surface area to volume brings the forces of surface tension into play. Surface forces are present whenever an air fluid interface is created. Work is required to create this interface and work can be recovered if the surface shrinks and the surface area decreases. Thus, a surface possesses free energy or the power to do work. The energy involved is proportional to the magnitude of the surface area.

Much of the elastic behavior of the lung is a result of this surface energy. This can be demonstrated by filling the lung with water which eliminates the air fluid interface and alters the elastic behavior. Relatively normal elastic behavior can be demonstrated in the air-filled excised lung even though tissue elasticity has been destroyed by treatment with alkali and elastase.[4]

The magnitude of the surface forces will depend on the nature of the air fluid interface. The surface tension of pure water is 72 dynes per cm. but is lowered considerably if a protein or oily film is present on the surface of the fluid. A lipid film is present at the air fluid interface in the alveoli, and this modifies the surface forces and influences the elastic behavior of the lung.[5] The presence of this film lends stability to the air-filled spaces and prevents collapse of spaces during normal function of the lung.

There is another advantage in the presence of small air spaces in the lung. Movement of gases in the terminal air spaces is by diffusion. If the air spaces were large a significant gradient of gas tension would exist. The small size of the alveoli reduces this gradient to an insignificant amount.

The Structure of the Alveolar Wall

The function of the alveoli is to permit ready exchange of oxygen and carbon dioxide between alveolar air and blood. To accomplish this the alveoli must be well ventilated with air, and the walls of the alveoli abundantly perfused with blood. Anatomic studies of the lung demonstrate numerous capillaries in the walls of the alveoli so that the walls appear to consist of a sheet of blood.

Separating the capillaries from the alveolar air is the alveolocapillary membrane. Electron microscopy has elucidated the nature of this structure.[6] The wall consists of the capillary endothelium with its basement membrane, the intermembranous space containing collagen and elastin, and the alveolar lining cells with their basement membrane. The most important observation is the remarkable thinness of the whole structure (average 1.3 micra).[3] This permits the ready diffusion of oxygen between alveolar air and capillary blood and, together with the huge surface area of the interior of the lung, allows for the large diffusing capacity of the lung.

The Connective Tissue Fibers of the Lung

The lung is not simply a series of small bubbles but has a solid structure which is constantly subjected to forces as the lung expands and recoils. If the lung did not contain structures with elasticity and high tensile strength the form could not be preserved over the lifetime of the individual. The connective tissue fibers in the lung serve such a purpose. These fibers are composed of fibrous proteins, collagen and elastin and form a network about the air-containing structures. The collagen fibers have high tensile strength, short range elasticity and a high modulus of elasticity. The elastin fibers are of lower tensile strength and have long-range rubber-like elasticity. The fibers are arranged in a helical* pattern about the alveolar ducts. This springlike arrangement permits collagen as well as elastin to contribute to the elastic properties of the lung.

---

*See Test Your Word Score Page 779.

The integrity of this network is essential to the normal structure and function of the lung but is often lost in the lungs of aged individuals. Increase in size of the air spaces, loss of septa and formation of abnormal air spaces result. The term emphysema is used to describe this process.

The Conducting of Airways of the Lung

The trachea and bronchi serve as passive conduits to permit movement of air to and from the lungs. The resistance to air flow is dependent on the size of these structures. The trachea is 2 cm. in diameter whereas the terminal bronchioles are 0.6 millimeters in diameter.

Resistance to Air Flow

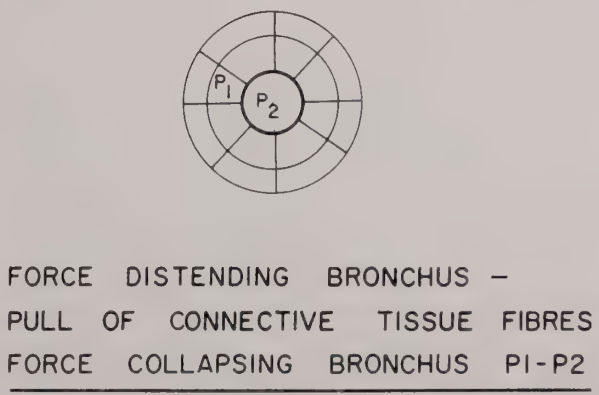
Intuitively one would think that the resistance to air flow in the smallest bronchi would be very great. This is not true. The resistance to flow is dependent not only on the size of the airways but on the velocity of air flow. If the total cross-sectional area of all the terminal bronchioles is very large, as indeed it is,[3] then the velocity of air flow will be small. One can make an analogy to the capillary bed of the vascular system where the vessels are tiny, the flow is slow, and the resistance not great. The location of increased resistance in diseases associated with diffuse bronchial obstruction such as bronchitis and bronchial asthma is quite another matter. Small bronchi can be obstructed and offer great resistance to flow.

Bronchial Obstruction

When bronchial obstruction is present the expiratory phase of breathing is predominantly affected. Inspiration may be accomplished with little difficulty. The explanation for the predominant expiratory nature of the obstruction in bronchitis and asthma is found in the structure of the lung. The larger bronchi contain plates of cartilage but in spite of this can undergo partial collapse with external pressure. The smaller bronchi have no supporting cartilage. The intrapulmonary bronchi are surrounded by air spaces as shown in Figure 1. Attached to the bronchi are connective tissue fibers which are part of the fibrous network of the lung. These connective tissue fibers exert traction outward and tend to expand the bronchi. The force exerted by these fibers will be a function of the degree of inflation of the lung. The difference in pressure between the alveoli (P_1) and lumen of the bronchus (P_2) will distend the bronchus during inspiration when the intra-alveolar pressure is negative and will tend to collapse the bronchus during expiration when the intra-alveolar pressure is positive. If bronchial obstruction is present and if expiration is forced, a large gradient will exist between the alveoli and bronchus, and P_1 will greatly exceed P_2. If the force created by this pressure difference exceeds the outward force from the fibrous network of the lung the bronchus will collapse. It is more likely to collapse when the lung is partially deflated than when it is fully inflated, because the tension exerted on the bronchus by the connective tissue fibers increases with increased inflation of the lung. Thus, the structure of the lung explains the familiar expiratory wheezing and the phenomenon of air trapping associated with bronchial obstruction.

Conclusion

The normal function of the lung is to a large extent dependent not only upon the anatomic arrangement of the structures but also upon their magnitude. The magnitude of the alveolar spaces permits the exposure of



P1
P2
FORCE DISTENDING BRONCHUS –
PULL OF CONNECTIVE TISSUE FIBRES
FORCE COLLAPSING BRONCHUS P1-P2

Fig. 1 — Forces impinging on a bronchus. The center circle represents the bronchus. The radiating lines represent connective tissue fibers. The spaces about the bronchus such as that labelled P_1 represent alveoli.

an enormous surface for exchange of oxygen between air and blood. The size of these spaces and their great surface area make surface energy an important determinant of lung function. The relationship between the size of the bronchi and the flow through them determines the resistance to movement of air. The thinness of the alveolocapillary membrane together with the great surface area of the lung permits the exchange of large volumes of oxygen during exercise without the development of hypoxia.

Diseases which modify the magnitude of these structures will result in malfunction of the lungs. Pulmonary emphysema consists of a loss of the normal structure of the peripheral air spaces. As one would surmise from the relationship between structure and function the disease produces profound changes in the function of the lungs.

IT'S THE LAW

Tests of Infants for Inborn Metabolic Errors Causing Mental Retardation

It is the duty of (1) the administrative officer or other person in charge of each institution caring for infants 28 days or less of age and (2) the person required in pursuance of the provisions of Minnesota Statutes, Section 144.159, to register the birth of a child, to cause to have administered to every such infant or child in its or his care *tests for phenylketonuria and other inborn errors of metabolism causing mental retardation* in accordance with rules or regulations prescribed by the state board of health. The provisions of this section shall not apply to any infant whose parents object thereto on the grounds that such tests and treatment conflict with their religious tenets and practice.

Effective Date. This act is effective on July 1, 1965.

The Physician's Rewards

By his training, by the human, moral and priestlike nature of his function, by the confidence he inspires and the gratitude he often deserves, the physician is one of the chiefs among the people. That is the way it has been and I do not see that it will ever be any different, no matter what changes are made in the political and social structures of our societies.

Quantitative Urine Culture with Calibrated Bacteriologic Loop

Office Laboratory Technique

S. T. SHAW, JR., M.D.*
M. HOPP, B.S.**
J. W. ST. GEME, JR., M.D.†
Minneapolis, Minnesota

QUANTITATIVE URINE cultures provide clinicians with a means for specific, accurate diagnosis of urinary tract infections. Because of the insidious, occult, and persistent aspects of some urinary tract infections, generous use of this method is indicated and calls for techniques which are simple, inexpensive, and potentially available to any laboratory including that of the doctor's office.

Routine use of quantitative urine cultures seems particularly applicable to a "high-risk population," notably diabetic, hypertensive, and gravid patients; or to a "suspect population," such as infants and children with fevers of unknown origin or failure to thrive; or, indeed, to apparently normal children and adults as part of routine medical evaluation.

It is the purpose of this paper to present a simple method for quantitating urine cultures, first described by Hoeprich[1] for use in hospital laboratories, utilizing a standard, calibrated bacteriological loop.

Methods

One hundred thirty-five urine specimens submitted for routine culture to our hospital diagnostic bacteriology laboratory were selected for parallel quantitative culture by the tube dilution and the calibrated loop method. Eosin-methylene blue and sheep blood agar petri plates comprised the diagnostic media used in each instance. Gram-stained smears were also obtained on 95 specimens cultured by the tube dilution and loop methods.

The tube dilution method used routinely in the laboratory involves pipetting 0.1 ml. of a 1:100 dilution of urine onto the surface of each agar plate. The 1:100 dilution of urine necessitates sequential ten-fold dilutions in two sterile dilution tubes containing physiological saline. The diluted urine is then streaked evenly over the surface of the agar plates with an ordinary bacteriologic loop. The cultures are incubated at 37° C. and the colonies counted after 24 hours. The number of colonies enumerated per plate, when multiplied by a factor of 1000, determines the number of bacteria in 1 ml. of the original urine.

*Medical Fellow, Department of Laboratory Medicine, University of Minnesota Medical School.

**Student Technologist Supervisor, Diagnostic Microbiology Laboratory, University of Minnesota Hospitals.

†Assistant Professor, Departments of Pediatrics, Microbiology and Laboratory Medicine, University of Minnesota Medical School, Medical Director, Diagnostic Microbiology Laboratory, University of Minnesota Hospitals.

This paper was presented in part at the fall meeting of the Northwest Pediatric Society on September 27, 1963.

The loop method involves the streaking of a loopful of undiluted urine over the agar surfaces, followed by 24-hour incubation. Colony counts are performed in the same manner as the dilution method. The loop,* having an inner diameter of 1.45 mm. and consisting of platinum (96.5%) and rhodium (3.5%) wire of 0.0016 inch diameter, is calibrated by the manufacturer to deliver a 0.001 ml. volume of fluid. Because of this delivery volume, the number of colonies per plate × 1000 yields the number of colonies per ml. Round, sterile urine bottles several centimeters in diameter are desirable since they provide, after thorough mixing of the specimen, a large bubble-free surface of urine into which the loop may be dipped. Besides the calibrated loop and sterile urine bottles, other necessary equipment includes an incubator, a Bunsen burner and sterile agar plates.

TABLE 1

Comparison (Specimen by Specimen) of Tube Dilution (1:1000) and Calibrated Loop (0.001 ml) Quantitative Assay

Number of Specimens	Cols./ml by Tube Dilution Assay	Results of Calibrated Loop Assay	Per Cent Positive Correlation
60	$>10^5$	58, Identical 2, $10^4 - 10^5$	96.6
19	$10^4 - 10^5$	18, Identical 1, $>10^5$	94.7
56	$<10^4$	53, Identical 2, 10^4 1, $>10^5$	94.6

TABLE 2

Comparison of Tube Dilution Assay (Cols./ml) with Gram Smears of Uncentrifuged Urine

Cols./ml by Tube Dilution Assay	Number of Specimens	Gram Smear Negative	Gram Smear Positive*
$<10^4$	35	32	3
$10^4 - 10^5$	13	4	9
$>10^5$	47	1	46

*A positive gram smear consists of at least two (2) bacteria per 20 oil immersion fields.

Results

In a simultaneous comparison of 135 urine specimens, 60 yielded greater than 10^5 cols./ml. by the tube dilution method (Table 1). Fifty-eight of these 60 specimens (96.6%) were in the same quantitative category (cols./ml.) by the loop technique. Nineteen specimens contained between 10^4 and 10^5 cols./ml. by dilution technique, and 18 of these (94.7%) fell into an identical quantitative category by the loop method. Of the 56 specimens containing less than 10^4 cols./ml. by the tube dilution method, 53 (94.6%) were identical by the calibrated loop method.

Gram-stained smears of uncentrifuged urine were found to be generally accurate (Table 2). Observation of at least two microorganisms per 20 oil-immersion fields was required to establish a gram smear as positive. Thirty-two smears were negative out of 35 urine specimens (91.4%) containing less than 10^4 cols./ml. by the tube dilution method. Of 13 samples with colony counts between 10^4 and 10^5 per ml., nine (69.2%) had positive smears. The 47 urine specimens yielding greater than 10^5 cols./ml. had 46 (97.9%) positive gram smears.

Discussion

The classical tube dilution-pour plate technique for quantitative urine cultures was described by Sanford et al.[2] in 1956. It has been shown by Kass and others[3] that for clinical interpretation the quantitation of such cultures in colonies per ml. may be divided into three categories. Urine specimens containing greater than 10^5 cols./ml. constitute infection; counts between 10^4 and 10^5 cols./ml. indicate infection or contamination; and counts less than 10^4 cols./ml. usually result from cutaneous contamination.

*Arthur H. Thomas Company, Catalogue No. 7433-C.

With simplified methods for bacteriologic quantitation of urine specimens, wide-spread patient survey in the clinic or office should be feasible. Quantitative studies would be extremely valuable from several standpoints. First, they provide a means for earlier diagnosis of insidious urinary tract infections. Second, evaluation of therapy would be significantly enhanced by frequent bacteriologic assay of active cases and prolonged follow-up cultures in "inactive" cases. Finally, data obtained from such studies should clarify our understanding of the incidence of urinary tract infections, their persistence, and their relationship to chronic or "healed" pyelonephritis. No one is in a better position to collect such data than the practitioner who may observe a patient population throughout many years, inclusive of initial therapy, intermittent laboratory evaluation, and, when necessary, necropsy study.

In this study, when compared to the tube dilution technique, the calibrated loop assay was approximately 95% accurate in the quantitation of uropathogens. Although the gram-stained smears of uncentrifuged urine were generally accurate, their sensitivity in the quantitative range of 10^4-10^5 cols./ml. was inferior to that of the loop method. Furthermore, the time required for inoculation, inspection, and interpretation of culture plates involved in the calibrated loop assay was found to be less than that required for preparation and microscopic examination of the gram smears. The loop technique offers the same advantage as the tube dilution-surface streak method in that positive cultures provide pure surface colonies which are often identifiable on the primary media after 24-hour incubation, or may easily be transferred to other media for further evaluation as well as for antimicrobial sensitivity studies. The majority of primary invaders can be identified on the original plates by an experienced observer without subculture. The most common uropathogen in the general population, Escherichia coli,[4,5,6] usually exhibits in colonial form an unmistakable green sheen on eosin-methylene blue agar plates. On the other hand, bacteriological screening based on microscopic examination of stained urine smears cannot provide the means for specific identification of the organism or evaluation of its sensitivity to antimicrobial agents.

Recent evaluation in our laboratory of two new methods for the quantitative culture of urine specimens, the triphenyltetrazolium chloride dye reduction test (Uroscreen*) and a paper strip-miniature rectangular agar plate assay (Uri-Tab**), have been found less suitable than the calibrated loop assay. Results of twenty-eight paired dye reduction tests and standard tube dilution assays correlated poorly, there being only 82% agreement. In addition, subculture of fluid from the Uroscreen tube would be necessary to retrieve and identify the infecting bacterium. Fifty-four similarly paired studies with the miniature agar plate assay revealed 82% agreement. The trypticase soy agar employed with the latter method would not allow simultaneous gross colonial indentification of the most common uropathogen, Escherichia coli.

Although the definitive diagnosis of many organisms and the evaluation of antimicrobial sensitivity of all organisms should be handled only by personnel skilled in bacteriological work, diagnostic screening and follow-up evaluation of therapy by quantitative urine culture is feasible for any small laboratory, including that of the practitioner's office, when the calibrated bacteriological loop is employed.

Summary

A simplified method for quantitative bacteriological culture of the urine employing a standard calibrated bacteriological loop is

**Uri-Tab, Dundee Laboratories, Inc.

accurate, yields pure bacterial colonies, and is well suited for widespread use in the office laboratory. The significant challenge of chronic pyelonephritis, its natural history and its eventuation from overt, subtle, or persistent urinary tract infection can be met by the practitioner in the office or clinic, using this tool for diagnosis and study.

This investigation was supported in part by a Public Health Service Fellowship (1-F2-HE-20, 664-01) from the National Heart Institute (Dr. Shaw).

WHAT'S YOUR DIAGNOSIS?

A 56-year-old printer working at his press was stricken suddenly with severe anterior chest pain radiating into the left arm. The pain persisted for three hours, until he was admitted to the hospital and the pain relieved with morphine. There had been no previous illness.

Physical examination revealed a blood pressure of 120/80. Heart rate 80 and regular. The heart tones were normal and no murmurs were heard. The lungs were clear. There were no other abnormal physical findings. The white count was 15,000 with 86 per cent pmns. SGOT transaminase levels were 10, 60 and 40 units on three successive days. ECG showed a Q wave, elevated S-T and negative T wave in leads III and a Vf characteristic of a posterior myocardial infarction.

A diagnosis of a posterior myocardial infarction was made and the patient treated with anticoagulation and bed rest. During the first week he had a rise in temperature to 100, which returned to normal on the sixth day. On this day the patient complained of sudden increase of chest pain and stated that he felt very ill. His temperature rose to 104. Blood pressure was 80/60 and a grade IV harsh, low-pitched systolic murmur was audible at the apex and near the sternum, and in this area a systolic thrill was also apparent. There were rales in both lung bases. The patient was digitalized. His temperature returned to normal during the second week and remained normal thereafter. He lived 45 days, always in heart failure or on the verge of it. He was never free of heart failure and was found dead in bed 45 days after his hospitalization. What is your diagnosis? A British scientist predicts that in time to come men will be born toothless. We thought, in our ignorance, that they usually were born that way. — Anon

Macroglobulins

HAROLD E. BELL, M.D.*
ELLENOR NEUMANN, M.Sc.**
Edmonton, Alberta

SINCE WALDENSTRÖM'S[1] description in 1944 of a series of patients whose serum contained markedly increased amounts of proteins with sedimentation constants in excess of 15 S20w, many techniques have been utilized by laboratories to increase the accuracy of identification and quantitation of these macroglobulins. Methods have included electrophoresis on a variety of media such as starch gel,[2] immunoelectrophoresis,[3] ultracentrifugation,[4] viscometry[5] and other immunochemical and physiochemical methods.[6]

The composition and structure of the three major groups of immunoglobulins, i.e., gamma-2 globulins, the gamma 1A globulins and the gamma 1M globulins, have been clarified by the work of Porter,[7] Cohen[8] and others. Immunologic methods have indicated the relation of macroglobulins in pathological states to normal serum globulins of the gamma 1M family.

This report concerns eight cases in which macroglobulins were found in increased amounts in the serum. They have been studied with paper and starch gel electrophoresis, immunoelectrophoresis, and ultracentrifugation techniques. Other simpler methods have also been employed. In addition, serum has been treated with penicillamine (ββ dimethylcysteine) to dissociate macroglobulins.[9]

Material and Methods

Eight sera containing pathological macroglobulins were examined. Of the eight patients studied, four had clinical evidence of primary macroglobulinemia. The remaining four had abnormal "M" bands on cellulose acetate or paper electrophoresis and rouleaux in the peripheral smear in conjunction with a mononuclear bone marrow infiltrate. Of the first seven cases, three presented with epistaxis, three with fatigue and weakness only, and one with pneumonia. These seven patients had varying combinations of hepatomegaly, splenomegaly and lymphadenopathy. The eighth patient is considered to be a case of lupus erythematosus.[4] All cases showed an excess of lymphocytes or abnormal mononuclear cells in the bone marrow as well as elevated sedimentation rates. None exhibited cryoglobulins. The amount of the macroglobulins found ranged from 680 mg./100 ml. to 3843 mg./100 ml. of serum. The S20w range was 14.9 to 17.16. All sera were separated from clotted blood immediately and stored at −5° C.

Total Serum Protein and Electrophoresis

Total serum protein was determined by the biuret method.[10] Paper electrophoresis was done with the Beckman Model "R" system. Bromphenol blue stained strips were scanned with a Model "RB" analytrol.

Starch Gel Electrophoresis

Vertical starch gel (11 %) electrophoresis[11] using Tris-borate 0.03M with respect to Tris, pH 8.02, for preparation of the gel and Borate Buffer 0.03M, pH 7.90 for the electrode compartment were utilized. Electrophoresis at 7 volts per cm. was continued for approximately four hours. Gels were sliced horizontally with a Buchler slicer and were stained with 1.14% Amidoschwarz 10B in a 5:1:5 water, acetic acid, methanol solution.

---

*Assistant Director, Department of Clinical Laboratory Services, University of Alberta Hospital.

**Department of Clinical Laboratory Services, University of Alberta Hospital.

Immunoelectrophoresis

Scheidegger's micromethod[12] with microscope slides was used. Two µl. serum was placed in a well in 1% agar in veronal buffer, pH 8.6, ionic strength 0.1 Separation was allowed to proceed for one hour at a 10V/cm. After filling the troughs with about 50 µl. of antiserum, diffusion was allowed to proceed for 20 hours. Unreacted proteins were washed out with 0.9% saline. This usually required 24 hours. Slides were dried, stained with Amidoschwarz 10B, and photographed.

Antisera

Polyvalent commercial horse antisera Lot 864-7 Immunology Inc., Chicago, Illinois, was used. Antigamma 1M(B2M) horse antisera lot 501-8 was obtained from Behringwerke, Frankfurt, (M) — Hoechst.

Penicillamine (ββ Dimethylcysteine) Treatment

A 100 µl. aliquot of whole serum to be tested was incubated with 25 µl. of a saturated solution of DL penicillamine in 0.85% saline for 12 hours at room temperature. A control specimen was incubated with saline only.

*Ultracentrifugation**

Ultracentrifugations were carried out at 59,780 r.p.m. (rev. min.) at 20° C. in a Spinco Model "E" machine with rotor temperature indicator control. Bar angles varied from 50° to 60°. Sera were diluted with 0.15 M NaCl. The usual corrections for temperature, density and viscosity using a $\overline{V}$ value of 0.73 were included in S20w calculations.

---

*We wish to thank Doctor C. Kay, Department of Biochemistry, University of Alberta, who did the ultracentrifuge determinations.

The concentration of each component was determined from the area under its peak from the frame exhibiting the best separation of the component.[13] The method of counting squares was used to determine the relative amounts of individual components.

No correction was made for the Johnston-Ogston effect.

Results

Ultracentrifuge Analysis

Ultracentrifuge studies in all cases showed components in S20w range of 14.9 to 17.16 in amounts ranging from 8.19% to 42.7% of total protein (Figure 1). On the basis of total protein determination these ranged from 680 mg./100 ml. to 3843 mg./100 ml. of total protein (Table 1). These values were considered to confirm the presence of a macroglobulinemia. All but Case 8 have clinical, hematological, and bone-marrow findings consistent with macroglobulinemia. Case 8 was a female diagnosed as having disseminated lupus erythematosus who had a positive L.E. clot test and an additional protein with an S20w of 9.47 at a concentration of 3.2%. She will be the subject of a subsequent report but at this time has no other evidence of Waldenstrom's macroglobulinemia.

Routine Laboratory Procedures

In six of eight cases the total protein was below or within the normal range of 6.4 to 7.9 gm./100 ml. for our laboratory. In only two cases was there an elevation. The total globulin was elevated above our normal range of 2.5 to 3.6 gm./100 ml. in four of eight cases. Four were within normal limits (Table 2).

The Sia water test was positive at some time in the course of the disease in six cases, but this was not a consistent finding. Bence Jones proteins were found in only one case.

Paper Electrophoresis

Paper electrophoresis runs were not all of the same duration. They showed that all but Case 4 had the increased protein in the gamma globulin range. Case 4 showed the macroglobulin close to the beta globulin band. No pattern characteristic of macroglobulins was identified (Figure 2).

Starch Gel

On starch gel electrophoresis results were not uniform. Six cases stayed in or close to the point of application. Case 4 which was in the beta region on paper electrophoresis migrated toward the anode (Figure 3). In Case 8 the site of the macroglobulin could not be definitely identified. On dissociation with penicillamine Cases 1,3,5,7 showed movement toward the cathode. On careful inspection with transmitted light in Cases 3,5,7, these appear to consist of two bands. Cases 2

and 6 showed four additional bands which had moved toward the anode in the beta region and which had not been seen in untreated specimens. Case 5 showed a large diffuse band which had moved anodally (Figure 4) and which on close inspection appeared to consist of four bands. A fifth band was present closer to the point of application. Case 8 showed no change with penicillamine treatment.

Immunoelectrophoresis

Using polyvalent antisera, a variety of patterns was seen (Figure 5). The macroglobulin remained at the well in Cases 1,3,8. In Case 2 an arc could be seen in the beta region. A diffuse band was seen in Case 5, but in others no abnormal arc was identified. In these cases no arc was seen at the usual gamma 1M site. When partially specific gamma 1M antisera was used on serum with and without penicillamine treatment the macroglobulin was identified in all cases. The site and shape of arcs was not uniform until the sera was treated with penicillamine. Penicillamine-treated sera showed a diffuse arc close to the trough in all cases (Figure 5).

Discussion

In this study of eight patients with abnormal amounts of macroglobulin, all but one (Case 8) had the evidence of macroglobulinemia of Waldenström. Total proteins or total globulins were not elevated in four patients and thus would not have indicated

*Patient not admitted to this hospital.

the need for further study. The Sia Test was positive in six of eight cases at some time in the course of the study but was not positive in two of the cases, despite levels of macroglobulins in excess of 8% of the total protein. These procedures would, therefore, appear to be inadequate for screening techniques.

Paper electrophoresis in all cases showed the presence of an abnormality in the beta-gamma globulin range. Although the type of abnormality could not be defined, the technique appears to be an effective screening procedure.

In starch gel six of eight cases showed little penetration of the gel from the point of application. In one case a broad band of protein, taken to be the macroglobulin, migrated anodally. In the eighth case gamma globulin was increased but no conclusion could be reached as to the site of the macroglobulin. With penicillamine treatment results were also variable. In four instances migration toward the cathode occurred and in three of these two new bands were seen. The appearance of two bands which migrate toward the cathode in reduced specimens has been previously reported.[14,15] In three cases, after reduction, four additional bands were noted which had migrated toward the anode but in Case 8 no change was noted. Better separation of the additional bands could have been achieved at a lower pH.[15]

When whole serum is treated with penicillamine, immunoglobulins other than macroglobulins may be dissociated, and the appearance of additional bands may not be due to the presence of abnormal macroglobulins. Repolymerization may also be an influencing factor. The macroglobulins examined were heterogeneous, and confirmation of macroglobulins is difficult when starch gel electrophoresis is used.

Immunoelectrophoresis utilizing a broad spectrum antiserum was not entirely satisfactory. The site of the macroglobulin varied, and in three cases it could not definitely be identified. It was felt to be obscured by the gamma 2 arc. Macroglobulins in increased amounts were demonstrated in all eight cases by using a partially specific antiserum and penicillamine treatment.

With the anti gamma 1M antiserum the position of the macroglobulin was readily apparent. By pre-treating the serum with penicillamine a distinct spread curve appeared close to the trough in all cases.

It therefore appears that immunoelectrophoresis, utilizing these conditions, provides a satisfactory method of confirming the presence of macroglobulins in increased amounts.

Ultracentrifugation has been used to confirm the presence of macroglobulins in all cases. Seven of the cases are clinically, hematologically and biochemically compatible with primary macroglobulinemia. The eighth case has been clinically diagnosed as disseminated lupus erythematosus. The macroglobulin level is much higher than is usually

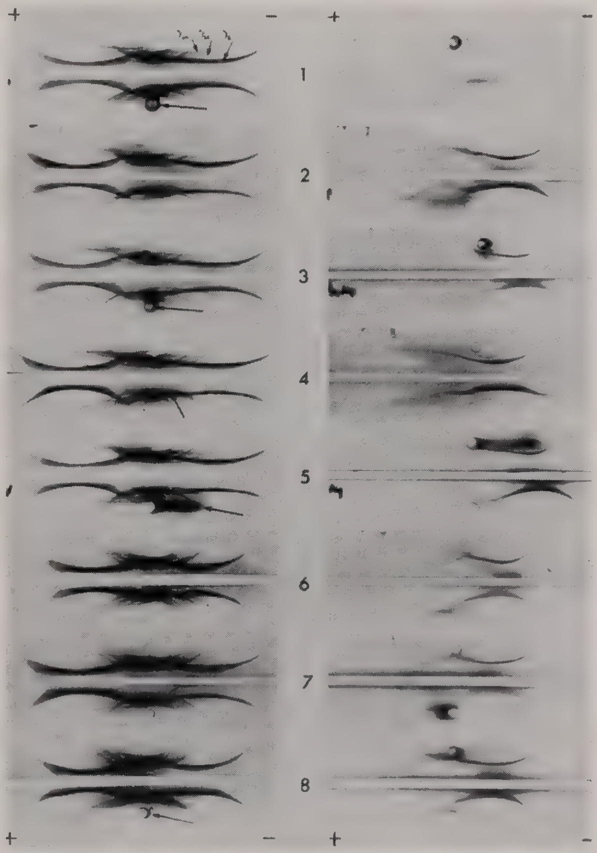

Fig. 5 — Immunoelectrophoretic Patterns. Each slide in the left column shows a normal control serum above and the patient's serum below, utilizing a broad spectrum antiserum. Macroglobulins are indicated with arrows. Each slide in the right column shows untreated patients' sera above and penicillamine-treated sera below using partially specific anti-gamma 1M anti-serum. A diffuse arc is noted in all penicillamine-treated sera.

noted in this disease. The diagnosis of primary macroglobulinemia on the basis of these protein studies should be made with caution and the possibility of secondary causes should be carefully considered.

Conclusion

A comparative study of the sera of eight patients which contained macroglobulins has been done using paper and starch gel electrophoresis, immunoelectrophoresis and ultracentrifugation as well as simpler procedures.

Total protein, total globulin and the Sia test were not effective as screening procedures. Paper electrophoresis showed that an abnormality was present in all cases.

Starch gel electrophoresis showed variable results which were difficult to interpret. Immunoelectrophoresis using partially specific gamma 1M antiserum, and penicillamine for dissociation, demonstrated the macroglobulin in all cases. Ultracentrifugation confirmed the presence of macroglobulins which had S20w's of 14.9 to 17.16 in amounts ranging from 8.19% to 42.7% of the total protein.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 752)

Autopsy revealed infarction of the interventricular septum and posterior wall of the heart with a large septal perforation. When a systolic murmur develops during the course of a myocardial infarction the most common cause is a rupture of the interventricular septum. Other conditions to be thought of are rupture of a papillary muscle, a friction rub misinterpreted as a systolic murmur, mitral insufficiency or ventricular aneurysm. In this case cardiac catheterization was done in the fourth week, demonstrating a tremendous left to right shunt at the ventricular level, confirming the clinical impression of ruptured septum.

Gratitude

And a doctor has very much to be thankful for also. Don't you ever forget it. It is such a pleasure to do a little good that a man should pay for the privilege instead of being paid for it. Still, of course, he has his home to keep up, and his wife and children to support. But his patients are his friends — or they should be so. He goes from house to house, and his step and his voice are loved and welcomed in each. What could a man ask for more than that? And besides, he is forced to be a good man. It is impossible for him to be anything else. How can a man spend his whole life in seeing suffering bravely borne, and yet remain a hard or a vicious man? It is a noble, generous, kindly profession. — Sir Arthur Conan Doyle (1859-1930)

Whenever you see a man with handkerchief, socks, and tie to match, you may be sure he is wearing a present. — Frank Case

Blood Transfusion Problems in Auto-Immune Hemolytic Anemia

EDMOND J. YUNIS, M.D.*
ROBERT A. BRIDGES, M.D.*
Minneapolis, Minnesota

FOLLOWING THE discovery of the antiglobulin reaction, Boorman et al.[1] established that some acquired hemolytic anemias show a positive direct antiglobulin reaction. Frequently the patients with auto-immune hemolytic anemia demonstrate an auto-antibody in the serum which agglutinates the erythrocytes of a large proportion of the blood donors tested.[2] For this reason, compatibility testing and transfusion of patients with auto-immune hemolytic anemia are very difficult.

The purpose of this article is to describe the serological investigations and compatibility testing of patients with auto-immune hemolytic anemia that is in current usage at the University of Minnesota Hospitals.

Clinical Material

Forty patients (23 females and 17 males) with positive Coombs tests and acquired hemolytic anemia were studied at the University of Minnesota Hospitals during a three-year period (1961-1964). All cases were referred to the Blood Bank for investigation of blood compatibility for transfusion.

Methods

The antibody in the serum was investigated for thermal reactivity by incubating 0.1 ml. of the patient's serum with 0.1 ml. of a 4% saline suspension of commercial test cells** at 4° C. and then at 37° C. for 60 minutes. This last incubation was followed by the antiglobulin reaction. A strong reaction at 4° C. indicated the presence of a cold antibody. In these cases, if the indirect Coombs test was found positive, the test was then repeated using washings with saline preheated at 37° C. before adding the antiglobulin serum. If the antibody was of the "cold type," the reaction was changed to negative or diminished considerably.

---

**Hemantigen. Knickerbocker Biologics, Pfizer Labs. Div., New York, N. Y.

Preparation of Eluted Cells and Erythrocyte Eluates

If the antibody had maximum reactivity at 4° C., the blood samples were kept refrigerated at 4° C. and the serum separated before use. The cells were obtained by crushing the clot, followed by separation of red cells and washing several times (four to six times) in normal saline (1 volume of cells in 9 of saline) until the supernatant of the last saline washing appeared clear of free hemoglobin. Erythrocyte eluates were prepared by means of 56° C. treatment described by Landsteiner[3] with 2 ml. of packed erythrocytes in 0.8 ml. of normal saline for 5-10 minutes, care being taken to keep the centrifuge cups heated with warm water (56° C.). The eluted cells were then washed three times with normal saline and a 4% suspension was prepared. The same procedure was used when the antibody had a maximum reactivity at 37° C., but the blood samples were left at 25° C. for 1-2 hours before separation of serum and preparation of eluate and eluted cells.

Blood Grouping and Antiglobulin Tests

ABO and Rh blood grouping, direct and indirect antiglobulin tests were performed as described in the "Technical Methods and Procedures of the AABB."[4] Eluted and noneluted cells were used for ABO and Rh grouping as well for the investigation of the I antigen with anti-I in cases of auto-immune hemolytic anemia of the "cold antibody type."

Identification of Cold Auto-antibody

The antibody was studied by using 0.1 ml. of serum and 0.1 ml. of a 4% saline suspension of erythrocytes: Group O Rh negative adult erythrocytes, group O Rh negative cord erythrocytes, eluted patient's cells, noneluted patient's cells and a commercial panel of cells.* The mixtures were incubated at 4° C., 25° C. and 37° C. for 60 minutes. The presence of agglutination in all tubes containing the adult erythrocytes and absence in the tube with the cord erythrocytes in the mixtures incubated at 4° C. and/or 25° C. was indication of anti-I specificity. During the course of this study we found that the readings at 25° C. more critically differentiated the anti-I specificity. (These data are shown in Table 3). The presence of similar agglu-

tination in all tubes indicated the presence of a nonspecific cold auto-antibody.

Identification of "Warm Auto-antibody"

The eluates and sera were tested with eluted cells, noneluted cells and a commercial panel of cells, using the indirect antiglobulin reaction. The presence of positive agglutination with patient's eluted and/or noneluted cells indicated the "auto-antibody" nature of the antibody. The specificity or nonspecificity of the antibody was determined by the pattern of positive agglutination reactions obtained.

Compatibility Testing of Patients with Auto-immune Hemolytic Anemia

At least fifteen donors were tested for blood compatibility with each patient with auto-immune hemolytic anemia. All donors had ABO and Rh grouping which was identical with the patient's grouping. If the auto-antibody was warm, the standard compatibility testing as described by the American Association of Blood Banks[4] was used. When the antibody studied was of the warm non-specific variety, all the tests (crossmatches) gave positive results, and those positive results giving a weaker degree of agglutination were chosen for transfusion.

When the antibody was of the cold type (anti-I or nonspecific) the crossmatches were performed as described above with one modification; the washings were done with saline warmed previously at 37° C. before adding the antiglobulin reagent. All donors giving negative or weak reactions in the preceding tests were then investigated at room temperature for 60 minutes. The donors giving the weakest reactions were used for the transfusions.

Results

Thermal Reactivity of Auto-antibodies of Auto-Immune Hemolytic Anemia

As can be seen in Table 1, there were 24 patients with auto-immune hemolytic anemia of the "cold antibody type" and 16 with the "warm antibody type." The etiology of the forty cases with auto-immune hemolytic anemia may also be seen in Table 1. Seventeen of these cases were classified as idiopathic, the remaining 23 as secondary or symptomatic according to the primary disease of the patient.

Specificity of Auto-antibodies of Auto-Immune Hemolytic Anemia

Only 26 out of the 40 cases reported here were studied for specificity of the auto-anti-

TABLE 2

Specificity of Auto-Antibodies of Auto-Immune Hemolytic Anemia

				Total
Primary Auto-Immune Hemolytic Anemia	Cold antibody type	"Nonspecific"	3	
		Anti-I	2	5
	Warm antibody type	"Nonspecific"	5	
		Anti-e	1	
		Anti-E	1	7
Secondary Auto-Immune Hemolytic Anemia	Cold antibody type	"Nonspecific"	3	
		Anti-I	2	5
	Warm antibody type	"Nonspecific"	8	
		Anti-e	1	9

The specificity of the cold auto-antibodies was studied in the patients' sera and of the warm auto-antibodies in the eluates obtained from the patients' erythrocytes. The two auto-antibodies directed against the e antigen were established after absorption of the eluates with E/E erythrocytes to remove a nonspecific reactivity which reacted weakly with E/E erythrocytes.

bodies. As shown in Table 2, of the 10 cold antibodies studied, four showed anti-I specificity, and of the 16 warm antibodies, two showed anti-e specificity and one anti-E specificity. The apparent nonspecificity of six of 10 cases of cold antibodies could be, in part, due to the relative strength of the I antigen on the cord cells as revealed at 4° C. Table 3 shows a comparison of the reciprocal titers of cold agglutinins (anti-I) using adult and cord erythrocytes. It shows that the three examples of auto-anti-I studies showed strong reactions with both cord and adult erythrocytes when incubating the mixtures at 4° C. but not at 25° C., wherein the reactions are sharply different. The antibodies give negative reactions with cord erythrocytes at 25° C. and positive reactions with adult erythrocytes. The auto-anti-I with the lowest titer showed differences of reactivity at both 4° C. and 25° C. The detection of anti-I should be performed by incubation of cord and adult erythrocytes with patient's serum at both 4° C. and 25° C. and not at 4° C. only, as performed in the six cases where we found nonspecificity.

Discussion

The auto-antibodies of auto-immune hemolytic anemia are classified according to their thermal reactivity as "cold antibodies" or "warm antibodies." Warm antibodies have an optimum temperature for reactivity of about 37° C., are nonhemagglutinating and are detected by the antiglobulin reaction. They are highly avid for the red cell surface and therefore best studied in eluates obtained from the patient's own erythrocytes. Cold antibodies have an optimum temperature of reactivity at 4° C. and are detected by direct hemagglutination. They are found in high titer in the serum, because they are not avid for the erythrocyte surface, especially at 37° C. We have reported here the serological studies of 40 patients with Coombs-positive hemolytic anemia, who were referred to us because of difficulty in compatibility for blood transfusion. Twenty-four patients demonstrated cold auto-antibodies and 16 warm antibodies. Four out of 10 cold antibodies studied for specificity demonstrated anti-I specificity and three out of 16 warm antibodies demonstrated anti-Rh specificity of some kind. These patients with anti-Rh specificity can be transfused with compatible blood. The "nonspecific" auto-antibodies react with most blood donors, and for this reason, the patients, if transfused, receive incompatible blood. These nonspecific auto-antibodies show different degrees of reactivi-

*The cold agglutinin titers were determined using 0.1 ml. of serial dilutions of the patient's serum and 0.1 ml. of a 4% saline suspension of erythrocytes of either Group O adult or cord blood. The mixtures were incubated for 60 minutes at 4°C., 25°C. and 37°C. The reciprocal of the last dilution which produced microscopic agglutination was recorded as the titer. The specificity of the cold agglutinin against I antigen was determined by the negative reactions obtained with i/i erythrocytes.

ties when tested with erythrocytes obtained from random donors. This is especially true when dealing with cold auto-antibodies.

An important contribution to the knowledge of auto-immune hemolytic anemia was made by Weiner et al.[5] when they described one case of auto-immune hemolytic anemia which yielded anti-e specificity in the eluate obtained from the patient's e/e erythrocytes. Since then several studies have pointed out frequent findings of warm auto-antibodies of hemolytic anemias directed to antigens of the Rh system — more frequently anti-e. Dacie[6] found in three sera that an apparently "nonspecific" antibody consisted of two components, one reacting with all cells tested and one reacting with all cells tested except -D-/-D-. W. Weiner extended these observations, demonstrating that 50 eluates from erythrocytes of patients with hemolytic anemia of the warm antibody type contain anti-Rh specificity of some kind.[7] They absorbed the eluates with Rh totally deleted (--/-- or dl), partially deleted (D--/D-- or pdl) and normal red cells (nl) and demonstrated three different specificities in the eluates directed against deleted, partially deleted and normal cells. In two examples of anti-e described by us in this article, the identification was possible after absorbing a nonspecific fraction with E/E erythrocytes before demonstrating two specificities: one versus the e antigen and one versus normal cells (nl).

Cold antibodies, on the other hand, have been known for several years to vary in the strength of their reactions with different cell samples from weak to very strong reactions. A. S. Wiener et al.[8] tested one serum of a patient with cold type antibody and described a new blood group system in 1956 — I blood group. The I negative individual i/i occurs about once in 20,000 donors. These persons have normally a "natural" anti-I. Auto-anti-I is usually found in people suffering from acquired hemolytic anemia of the cold antibody type, even though their eluted cells demonstrate the I antigen. Jenkins et al.[9] reported that cord cells gave relatively very weak reactions with powerful anti-I and failed to react at all with the less powerful anti-I. We found this to be true only when the reactions with cord and adult erythrocytes were carried out at 25°C. and not at 4°C. This partially explains the incidence of nonspecificity of cold antibodies which have been studied only at 4°C. At that temperature we have shown that the I antigen appears relatively strong in cord cells. In practice it is difficult to find donors i/i to transfuse patients with auto-anti-I. Transfusion of such patients and of patients with "nonspecific" warm auto-antibodies is indicated only as an emergency procedure to palliate severe symptoms of anemia-decompensation. With the procedures described here the patients are transfused with the donors which show the weakest degree of agglutination. It has been recommended[10] to transfuse the patient with 50 ml. of erythrocytes after obtaining a serum bilirubin and hemoglobin level. Four hours later determine the bilirubin again. A rise of bilirubin of less than .5 mg. is good evidence of not rapid erythrocyte destruction which allows the transfusion of the rest of the packed cells. Follow-up determinations of hemoglobin and bilirubin may give a better indication of benefit gained from the transfusion.

Summary

1. Forty patients with positive Coombs test and acquired hemolytic anemia were studied serologically and classified clinically according to the etiology of the hemolytic process. In seventeen cases no etiology could be determined to explain the hemolytic process; these were diagnosed as idiopathic auto-immune hemolytic anemia. The remaining twenty-three were symptomatic or secondary to the primary disease of the patient.

2. There were 24 patients with "cold antibody type" auto-immune hemolytic anemia and 16 patients with "warm antibody type" auto-immune hemolytic anemia.

3. The specificity of cold auto-antibodies was studied with the patients' sera and of warm auto-antibodies with eluates obtained from the patients' erythrocytes. Ten cold auto-antibodies were studied to determine anti-I specificity. In four cases the antibodies gave strong agglutination of adult

erythrocytes and negative reactions of cord erythrocytes following incubation at room temperature (25°C.) for 60 minutes and were classified as anti-I. Eluates obtained from the erythrocytes of 16 cases with warm antibody type were studied, showing specificity against the *e* antigen in two patients and against the E antigen in one case.

4. Transfusion of patients with autoimmune hemolytic anemia is always difficult because the crossmatches are regularly positive. We have described the procedures used in our laboratory to find the least incompatible blood for transfusion.

June 1966 Medical License Examination

At the February 11-12, 1966 meeting of this Board a request made by the President of the Senior Medical Class of the University of Minnesota Medical School was given consideration.

It was the determination of the Board that the request could be granted and the regular June 1966 examination (which would regularly be held June 21, 22 and 23, 1966) was re-scheduled for June 14, 15 and 16, 1966, in order to accommodate graduates who wish to leave for their internships.

The man who has not anything to boast of but his illustrious ancestors is like a potato — the only good belonging to him is underground. — Thomas Overbury

---

The thumb takes the responsibility, the index finger the initiative. — Chazal

The Bedside Manner

Since the memory of man runneth not to the contrary the medical fraternity has been invested with its own distinctive mystique. Even the shaman had his aura!

Whence derives this indefinable, almost esoteric quality?

From its beginnings medicine developed its professional code and its *esprit de corps,* concurrently with its body and practice: a dual evolution much like that of English common law.

By Chaucer's time the doctors' deportment code was fairly well crystallized — as expounded by the trio of 14th century Johns: John of Gaddesden, John of Mirfield, and John of Arderne. A few provocative and illuminating gems, selected at random from that code, read as follows:

"Do not walk hastily, which betokens levity, or too slowly, which is a sign of faint-heartedness.

"When called to a patient, find out from his messenger as much about him as you can before you arrive. Then, if his pulse and urine tell you nothing, you can still surprise him with your knowledge of his condition.

"When feeling the patient's pulse, allow for the fact that he may be disturbed by your arrival and by the thought of the fee you are going to charge him.

"Hide your instruments from the sight of the patient — and from other doctors.

"Tell the patient that, with God's help, you hope to cure him, but inform the relatives that the case is grave. Then, if he dies, you will have safeguarded yourself. If he recovers, it will be a testimony to your skill and wisdom. When asked how long recovery will take, specify double the expected period. A quicker recovery will redound to your credit, whereas if a patient finds the cure taking longer than prophesied, he will lose faith in your skill. If he asks why the cure was so swift, tell him he was strong-hearted and had good healing flesh; he will then be proud and delighted.

"Do not sow dissension among the servants or offer them unsolicited advice, or brawl with anybody in the house.

"If you are asked to dinner, do not be over-effusive in your gratitude, and do not quibble about accepting the place of honour at the table. Be neither indiscreet nor exacting. Do not criticise the food, even if it is millet bread which turns your stomach. Stay sober. During the meal, enquire frequently after the patient, lest he suspect that you have forgotten him in your enjoyment of his viands.

"Tell the patient funny stories as well as recommending him to serious contemplations and to the Scriptures.

"If you do not wish to take on a case, pretend to be ill.

"If you find the patient dead on your arrival, show no surprise. Say you knew from the account of his symptoms he would not recover and enquire the hour at which he died. This will enhance your professional reputation.

"Missing from this list of instructions is the maxim which used to be quoted to medical students of a later day: 'The first thing to learn is not to kick the pot under the bed.' Also missing is the advice given by William of Salicet to the surgeon of the thirteenth century: 'A wise surgeon will refrain from stealing while he is in attendance on a patient.' "*

Flagyl destroys trichomonads
here & here & here & here
No topical treatment can

Flagyl®

brand of
metronidazole

Flagyl eliminates the difficulties and frustrations that have long attended the treatment of trichomonal infection.

These difficulties arose mainly from:

1) the failure of any previously known agent to destroy the protozoan in paravaginal crypts and glands;

2) the failure of any previously known agent to prevent reinfection by eradicating the disease in male consorts.

The introduction of Flagyl removed both of these long-standing deficiencies. Hundreds of published investigations in thousands of patients have confirmed the ability of Flagyl to cure trichomoniasis.

Correctly used, with due attention to repeat courses of treatment for resistant, deep-seated invasion and to the presumption of reinfection from male consorts, Flagyl has repeatedly produced a cure rate of up to 100 per cent in large series of patients.

Nothing cures trichomoniasis like Flagyl.

Dosage and Administration

In *women:* one 250-mg. oral tablet t.i.d. for ten days. A vaginal insert of 500 mg. is available for local therapy when desired. When the inserts are used one vaginal insert should be placed high in the vaginal vault each day for ten days, and concurrently two oral tablets should be taken daily.

In *men:* in whom trichomonads have been demonstrated, one 250-mg. oral tablet b.i.d. for ten days.

Contraindications

Pregnancy; disease of the central nervous system; evidence or history of blood dyscrasia.

Precautions and Side Effects

Complete blood cell counts should be made before and after therapy, especially if a second course is necessary.

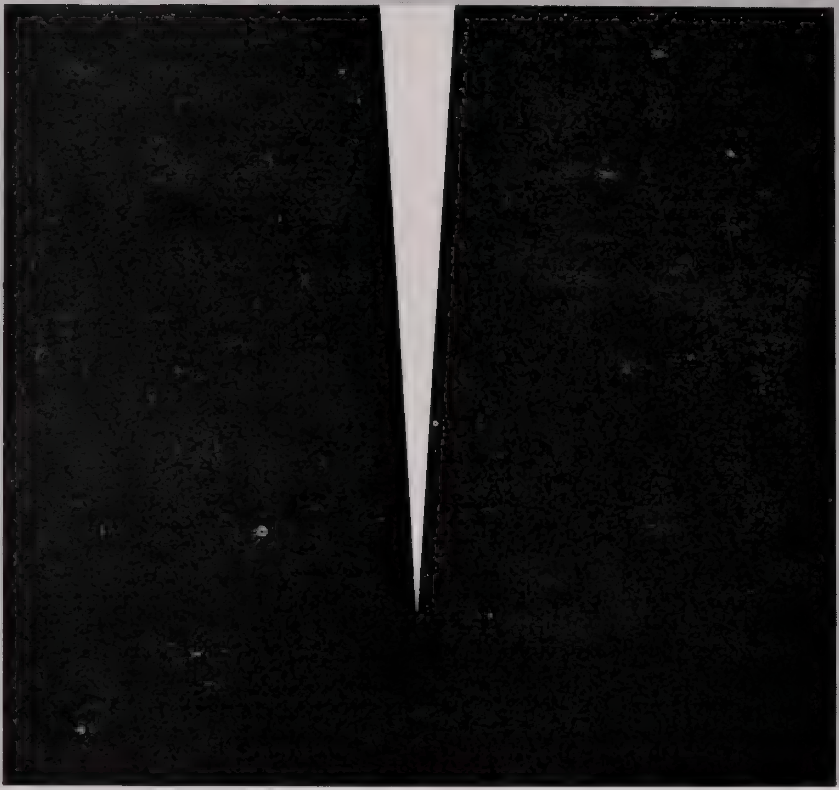
Infrequent and minor side effects include: nausea, unpleasant taste, furry tongue, headache, darkened urine, diarrhea, dizziness, dryness of mouth or vagina, skin rash, dysuria, depression, insomnia, edema. Elimination of trichomonads may aggravate moniliasis.

Dosage Forms

Oral–250-mg. tablets/Vaginal–500-mg. inserts

SEARLE

Research in the Service of Medicine



incisive

A good way to describe 'Stelazine'. It's different from the tranquilizers that sedate and dull your anxious patients. Its antianxiety effect is direct. On 'Stelazine', your patients can be calmed yet remain alert.

And 'Stelazine' offers additional benefits. Dependence has not been reported. At low doses, side effects are minimal. Its b.i.d. dosage is convenient and economical.

Stelazine®

brand of **trifluoperazine**

Indications: Symptoms of excessive anxiety. *Contraindicated* in comatose or greatly depressed states due to CNS depressants and in cases of existing blood dyscrasias, bone marrow depression and pre-existing liver damage. *Principal side effects,* usually dose related, may include mild skin reaction, dry mouth, insomnia, fatigue, drowsiness, dizziness and neuromuscular (extrapyramidal) reactions. Muscular weakness, anorexia, rash, lactation and blurred vision may also be observed. Blood dyscrasias and jaundice have been extremely rare. Use with caution in patients with impaired cardiovascular systems. Before prescribing, see SK&F product Prescribing Information.

Gerald Taylor Evans, M.D., Ph.D.

THIS ISSUE OF MINNESOTA MEDICINE honors Gerald Taylor Evans, M.D., Ph.D., on the occasion of his twenty-fifth year at the University of Minnesota.

During the years since he came to Minnesota from Yale in 1939 Dr. Evans has made the University of Minnesota a leader in the field of Laboratory Medicine, viewed throughout the country as a foremost example of what can be accomplished in this field.

Gerald Taylor Evans was born March 11, 1900, in Galt, Ontario. After attending the University of British Columbia, he taught school in British Columbia before entering the McGill University Medical School in 1926. Following graduation, he continued graduate studies at McGill and the University of Pennsylvania, receiving the degree of Doctor of Philosophy from the latter institution in 1937. He was a member of the faculty in physiological chemistry at Yale University School of Medicine before coming to Minnesota as director of the clinical laboratory services in 1939. Under his leadership these services and their educational programs formed the Department of Laboratory Medicine in 1959, with Dr. Evans as Professor and Head of the new department.

This event was a momentous occasion. The department was the first Department of Laboratory Medicine in the United States, establishing a pattern of organization which is being repeated by other medical schools. The department is a monument to Dr. Evans' foresight and pioneering spirit.

On November 20 and 21, 1964, students and colleagues from all over the United States gathered in Minneapolis to honor Dr. and Mrs. Evans. A Silver Anniversary Symposium was held on those days. The program was made up of papers presented by colleagues and students. The original articles presented here originated from papers presented at the Evans' Symposium.

Gerald Evans has made many outstanding and lasting contributions to the medical school, to the state and to medicine in general. The most important of these lie in the following areas:

(1) The development of medical technology education.

(2) The development of high standards of clinical laboratory service.

(3) Postgraduate education in clinical pathology.

(4) His strong influence on many young

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

people in medicine, inculcating a devotion to the highest ideals of medical practice, scholarship and science, has been and still is one of his greatest gifts.

When Gerald Evans came to Minnesota, he first undertook a strong pioneering development of an educational program in medical technology. Under his guidance, the course in medical technology at the University of Minnesota became generally considered the outstanding one in this country. Meticulous attention to high educational standards of technical excellence and professional ideals characterized this effort.

Next was undertaken the development of strong, versatile clinical laboratories in which careful attentiveness was directed especially toward quality of service. This effort was speeded forward by medical technologists, intelligent, able, with independent judgment, and schooled in the ideals of technical excellence and dedication to service which Dr. Evans had engendered.

Later, a sound program was established for the training of physicians in clinical pathology. This program accented graduate study through individual research and scholarship and exerted the same emphasis on intelligent attention to detail at the bench and on the wards, as have all of the efforts initiated by Dr. Evans.

Dr. Evans has always taken a vital interest in the teaching of medical students. The course in Laboratory Medicine in the sophomore year, a course which largely grew from his plans, emphasizes the use of the laboratory in the care of patients. The course, as he evolved it, is one which is closely related to clinical medicine: taking up laboratory topics and relating them to clinical situations in the diagnosis and care of patients. It illustrates well his concept of the supreme relevance of the laboratory to patient care, rather than a self-contained importance of the laboratory.

Gerry Evans has conceived of Laboratory Medicine as an island between the clinical fields and the basic medical sciences. Laboratory Medicine draws material and ideas from the basic sciences and makes them relevant to clinical medicine toward the goals of more perfect diagnosis and management of patients and, indeed, improvement and prolongation of human life.

He has been a kindly but firm and perceptive teacher and preceptor. Through his influence many young people have been motivated to seek goals they had not envisioned and to realize individual potentials of which they were not aware. Most of all, those who are proud to have been his students take pride in his imprimatur, an emphasis on quality of effort together with alert and informed sensitivity to the patient and his welfare.

Gerald Evans made several key decisions which were amazingly far-sighted in the formative years of Laboratory Medicine at Minnesota. Though his hand and mind were highly creative, he did not publish much of his thought and accomplishment. That which he did write was circularized to a few medical educators, hospital administrators and other colleagues and had immense impact on the course of developments at Minnesota and other institutions. Affectionately known as his Opus, it was written in 1959, and many of its passages are as cogent and predictive today as then. He has delineated in this "opus" a blueprint for the further development of Laboratory Medicine, pertinent not only to Minnesota but to other institutions as well.

Some words he wrote a few years ago concerning training in clinical pathology illustrate well the concepts which have guided his activities at Minnesota:

"We are in a technological revolution of an unprecedented nature. Our branch of the profession has the best intrinsic potential for measuring up to the new challenge in productive medicine.

"We are at the crossroads. Trade-vocational-apprenticeship type training is outmoded and should largely be abolished. Training should be planned, thorough, fundamental and flexible.

"Quality should be the lead objective. Although our trained members should have a broad viewpoint, they should not be generalists, professing comprehensive superficiality. Whether the individual is the pathologist, the

SQUIBB Squibb Quality—the Priceless Ingredient

teacher or the highly specialized investigator (or all three), it is the *man* who should be trained and at a high level.

"There is an indivisibility of research, education and improved, even revolutionized, service."

Though these words were written concerning clinical pathology, they also pertain in many essentials to his thoughts about medical technology.

Gerald Evans has been a pioneer, a prophet, a planner, yes, even a dreamer, though many of his dreams will not come true for many years hence. Those who follow him at the University of Minnesota are immensely in his debt. He has set his department on a path which, if energetically and intelligently followed, will bring increasingly rich rewards to the University of Minnesota, to the state of Minnesota and to the professions which make up Laboratory Medicine as a whole.

Ellis S. Benson, M.D.*

Laboratory Medicine — A Prospectus

THE CONTRIBUTION of the clinical laboratory to the diagnosis and management of patients has been accepted for many years. It therefore seems difficult to believe that the major growth of hospital laboratories has occurred during the past 25 years. Accordingly, it is appropriate to review several of the major trends which have developed during this recent period and to speculate on some of the developments which may be anticipated during the next 25 years. These developments will reflect improvements in scientific instrumentation, including advances in automation and data-processing techniques. Philosophically, they will recognize the increasingly important role of both outpatient and preventive medicine.

Specifically, what can be anticipated? Classically there are three major avenues of gathering information with reference to patient management: the history, the physical examination, and the laboratory examination. The roles of the history and the physical examination have become relatively well established. The role of the laboratory examination is rapidly changing, however, and may be expected to change even more dramatically in coming years. It is now accepted practice to gather historical information and physical findings concerning all of the major systems of the body at the time of a detailed clinical examination. It will soon be feasible to provide a similar laboratory examination which will reflect information regarding many of the major systems of the body. Such a battery of tests will be directly analagous to the current screening type of physical examination which provides information regarding heart, lungs, liver, etc. Laboratory examinations of this type will be performed at the time of hospital admission, as well as during periodic health examinations. Information gathered from such examinations will be recorded in a form facilitating retrieval and will be helpful in detecting asymptomatic pathology, in facilitating earlier diagnoses, and in shortening periods of hospitalization. Data will be considered not only on the basis of what is normal in the general population, but what may be considered normal for an individual of a specific age and sex. In addition, compilation of such information will facilitate establishing normal values for given individuals. Values which could be considered normal in reference to norms based on the general population may appear abnormal when considered in reference to a patient's own established "normal values."

In addition to laboratory screening batteries, clinicians will have new tests available which are of importance in the management of specific clinical problems. Many of these tests will not be of general value and hence will not be incorporated in screening batter-

An antibiotic of choice is one that works

TAO works

Susceptibility Results
Staphylococci [2,3,1]

# OF CULTURES	YEAR	% EFFECTIVE
6,725	1962	88.6%
5,440	1963	88.0%
10,384	1964	88.5%

β-Hemolytic Streptococci [2,3,1]

# OF CULTURES	YEAR	% EFFECTIVE
2,448	1962	89.5%
1,519	1963	95.2%
2,492	1964	96.7%

The Product

In a world study of antibiotics ***in vitro***[1], TAO had an overall effectiveness of 87.3%, higher than chloramphenicol and erythromycin, and significantly higher than tetracycline and penicillin.

The Plus... Consistent Performance

Yet antibiotics must not only work. They must work consistently. Here are the results from the largest study of microbial susceptibility ever undertaken. In 29,048 cultures of overt staphylococcal and β-hemolytic streptococcal infections, note the consistency of results with TAO.

TAO®

[triacetyloleandomycin]

J. B. Roerig and Company, New York, New York 10017
Division, Chas. Pfizer & Co., Inc., Science for the World's Well-Being®

TAO Rx information

Indications: The bacterial spectrum includes: streptococci, staphylocci, pneumococci and gonococci. Recommended for acute, severe infections where adequate sensitivity testing has demonstrated susceptibility to this antibiotic and resistance to less toxic agents. **Contraindications and Precautions**: TAO (triacetyloleandomycin) is not recommended for prophylaxis or in the treatment of infectious processes which may require more than ten days continuous therapy. In view of the possible hepatotoxicity of this drug when therapy beyond ten days proves necessary, other less toxic agents, of course, should be used. If clinical judgement dictates continuation of therapy for longer periods, serial monitoring of liver profile is recommended, and the drug should be discontinued at the first evidence of any form of liver abnormality. It is contraindicated in pre-existing liver disease or dysfunction, and in individuals who have shown hypersensitivity to the drug. Although reactions of an allergic nature are infrequent and seldom severe, those of the anaphylactoid type have occurred on rare occasions. **References**: 1. Isenberg, Henry D.: Health Laboratory Science **2**:163-173 (July) 1965. 2. Fowler, J. Ralph et al: Clinical Medicine **70**:547 (Mar.) 1963. 3. Isenberg, Henry D.: Health Laboratory Science **1**:185-256 (July-Aug.) 1964.

ies. For particular patients with particular pathologies such tests will be invaluable, however, and accordingly, the number of investigations performed by clinical laboratories will continue to increase.

Laboratory growth is accelerating and, in response to the clinicians' requests, the number of determinations performed in hospital laboratories is currently increasing at a rate of 10-30% annually. As would be expected, the trends discussed above are already in progress. Automation in the clinical laboratory, systems of data retrieval, computer techniques, and new analytic methods are currently the subjects of numerous national and international meetings and symposia. On the basis of these developments one may predict that clinicians will receive increasingly better support from clinical laboratories during the next 25 years. If one considers these current trends in laboratory medicine in conjunction with the advances which may be anticipated in other diagnostic methods and in therapeutic techniques, accelerated improvement in patient care appears inevitable.

The Future of Medical Technology

DOES MEDICAL TECHNOLOGY as a separate professional entity have a future or will it be absorbed and replaced by specialists in laboratory medicine?

From a practical standpoint Medical Technology must continue to exist as a separate professional entity because physicians and hospitals require versatility in technological skills. The usual volume of demands does not warrant specialists. Another practical consideration is that in hospitals technologists must be available for emergencies, and involving several people in this emergency activity becomes economically prohibitive.

Practical expediency, however, cannot be the basis for the existence of a profession. If Medical Technologists did not exist, solutions would be found to practical problems, primarily by the substitutions of nonprofessional personnel trained in a few techniques or by joint utilization of facilities and personnel between neighboring institutions. The consequences of this kind of limited laboratory service to patient care could be disastrous. The unique resource of the profession needs evaluation and definition. How does a Medical Technologist differ from a technician in the laboratory? A technician knows how to perform certain techniques but a technologist also knows why. The technologist is trained to think and to apply principles, even when confronted with an unfamiliar test.

With the increasing variety and complexity of laboratory determinations the profession of Medical Technology must modify its training and its operation towards increased application of basic knowledge rather than increased technical maneuvers. The correlation of basic chemical and biological principles to clinical application must be emphasized. Less time should be devoted to so-called "bench" training and more time to guided investigation of application of principles in established methods and in new procedures. Medical Technology can offer something unique to patient care, viz., the individual who has the basic knowledge in all laboratory fields and who can apply this knowledge to new situations and demands. The future is broad for Medical Technology; but only a self-inflicted amputation from tradition and a complete prosthesis can realize that future.

Butazolidin® alka

phenylbutazone	100 mg.
dried aluminum hydroxide gel	100 mg.
magnesium trisilicate	150 mg.
homatropine methylbromide	1.25 mg.

In rheumatoid arthritis–effective thera
with minimal chance of G-I upset

Therapeutic Effects
Fifty to 75% of patients obtain major relief of arthritic symptoms, as reported by numerous clinicians. In addition, the problem of gastric upset—a major problem with certain other oral antiarthritic agents—is minimized by the presence of antacids and an antispasmodic in the formulation.

Improvement is generally seen within 3 to 4 days, and trial therapy need not be continued beyond a week. Relief of pain is followed quickly by resolution of inflammation and improved joint function. Relief of symptoms is often accompanied by increased appetite, gain in weight and an improved sense of well-being.

The initial response is usually maintained without dosage increases; indeed, initial dosage is often reduced for maintenance purposes.

Salicylate or steroid therapy can usually be diminished or, in some instances, eliminated.

Contraindications
Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. Because of the increased possibility of toxic reactions, the drug should not be given when the patient is senile or when other potent chemotherapeutic agents are given concurrently. Large doses of Butazolidin alka are contraindicated in patients with glaucoma.

Precautions
Before prescribing, the physician should obtain a detailed history and perform a complete physical and laboratory examination, including a blood count. The patient should be kept under close supervision and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools. Regular blood counts should be made. The drug should be used with greater care in the elderly.

Warning
If coumarin-type anticoagulants are given simultaneously, the physician should watch for excessive increase in prothrombin time.

Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea and sulfonamide-type agents and insulin. Patients receiving such concomitant therapy should be carefully observed for this effect.

Adverse Reactions
The most common adverse reactions are nausea, edema and drug rash. The drug may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, generalized allergic reaction, stomatitis, salivary gland enlargement, vertigo and languor may
occur. Leukemia and leukemoid react
have been reported but cannot definit
attributed to the drug. Thrombocytope
purpura and aplastic anemia are also
sible side effects. Confusional states,
agitation, headache, blurred vision, op
neuritis and transient hearing loss hav
been reported, as have hepatitis, jaun
and several cases of anuria and hemat
With long-term use, reversible thyroid
hyperplasia may occur infrequently.

Average Dosage in Rheumatoid Arthri
Initial: 3 to 6 capsules daily in divided
It is usually unnecessary to exceed 4 c
sules daily. A trial period of 1 week is a
quate to determine response; in the ab
of favorable response, discontinue.

Maintenance: An effective level is ofte
achieved with 1 to 2 capsules daily; do
exceed 4 daily.

Also available:
Butazolidin®, phenylbutazone
Tablets of 100 mg.

The Uncertain Year of 1916

THE FOREBODING year of 1916 was indeed one to remember. Early in March, Pancho Villa and his boisterous guerillas raided Columbus, New Mexico, and were pursued by an American brigadier general then almost wholly unknown to the public — John J. Pershing. Lord Kitchener of Khartoum, Britain's hope for leadership in World War I, in June was drowned at sea on his way to Russia on a military mission. Sir Roger Casement, the quixotic Irish patriot, was hanged in London in August; after an exciting election evening in November, Mr. Justice Charles Evans Hughes went to bed, and his confident aides told inquiring newspapermen: "The President has retired for the night." The next morning, however, Mr. Hughes discovered that Woodrow Wilson was the President and that he was not. Nearly everyone sensed that America would go to war, but very few found any pleasure in the premonition.

The best-selling new novels of 1916 were *Tish,* by Mary Roberts Rinehart; and *Penrod and Sam,* by Booth Tarkington. On the stage Ethel Barrymore was a great success as the lady drummer in Edna Ferber's "Our Mrs. McChesney," and the male idol of the moment was William Faversham in George Bernard Shaw's "Getting Married." In American homes pianos were banging out "K-K-Katy, Beautiful Katy," and "Tipperary," and William Farnum and Mary Miles Minter were the reigning peers of an infant motion-picture industry. Elsie Janis and Sir Harry Lauder were supreme on the vaudeville stage.

It has been my privilege to know intimately two of the men who were graduated in medicine in 1916 and who thus became members this year of the "Fifty Club" of the Minnesota State Medical Association. One is Dr. Harry LeRoy Smith and the other is Dr. Austin C. Davis, both internists, both my colleagues and both members of the same class in the State University of Iowa College of Medicine. Both were superlatively fine practitioners, gifted with perceptive intuition, superior clinical judgment and the rare capacity for long hours of hard work and the stamina to sustain them.

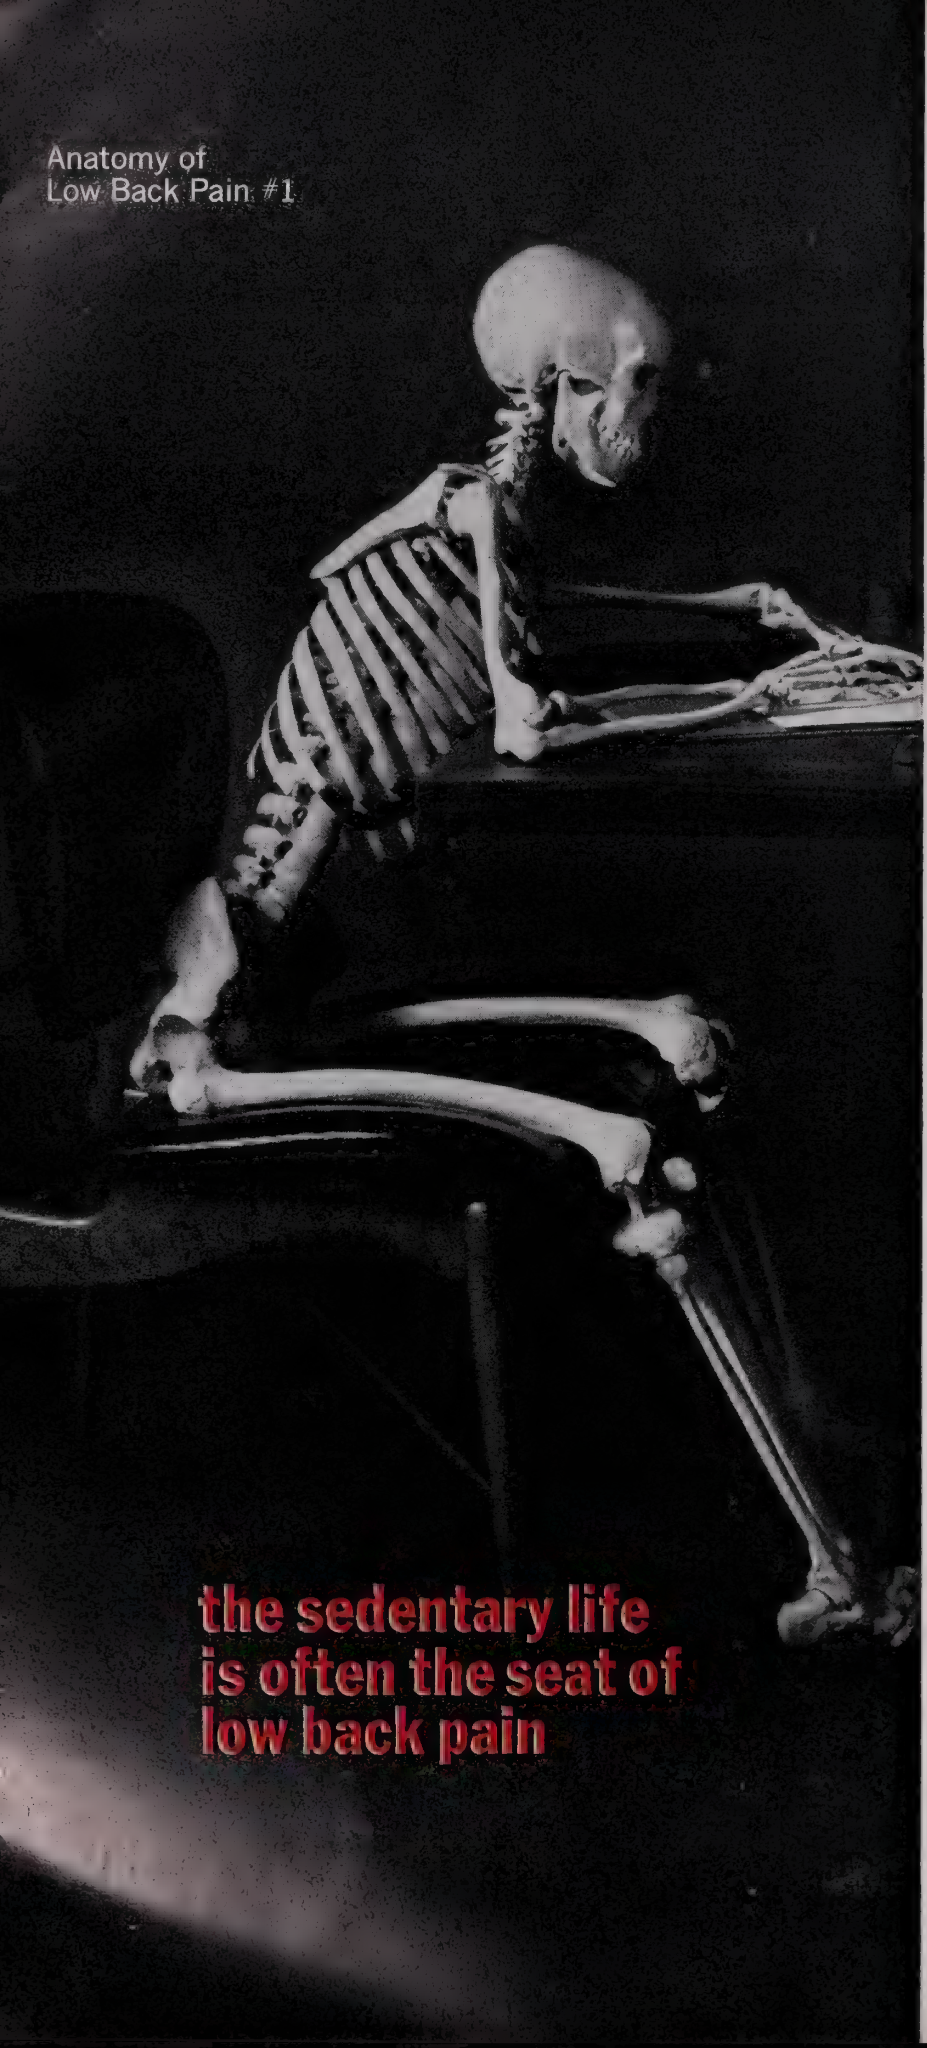
Dr. Davis in 1916 was an intern in the State University of Iowa Hospitals. He followed the course of most young medical graduates of that era by going into the Army Medical Corps in 1917; then he returned to his university to lecture on medicine until 1923, when he was appointed a first assistant in medicine in the Mayo Clinic. He became a member of the staff of the Mayo Clinic and remained so until his retirement on October 1, 1956. At that time he had attained the rank of assistant professor of medicine in the Mayo Graduate School of Medicine, and since that time he has lived in Pompano Beach, Florida.

It is fortunate for most of us that men like Austin Davis do not come along very often, for in this instance emulation would be difficult indeed or, what is nearer the truth, impossible of success. His keen intellect and profound discernment were accompanied by a quiet humor and an unfailing gentleness of nature; he was never obtrusive and was ever courteous, yet he had within him an abundance of natural gifts which a lesser man would have exploited with an aggressiveness and an indifference to others abhorrent to Austin Davis and alien to his character.

Dr. H. L. Smith, graduating in medicine with Austin Davis in 1916 at the State University of Iowa, was an intern at the Vancouver General Hospital until November, 1917, when he, too, entered the Army Medical Corps for service in France. His war experiences he narrated vividly in 1940 in his book, *Memoirs of an Ambulance Company Officer.* They show that wherever the fighting was, there also was Roy Smith. He returned to Walnut, Iowa, where until 1925 he carried on the vastly instructive and personally satisfying practice of a small-town physician. Then he came to Rochester as a fellow in medicine of the Mayo Graduate School of Medicine; he was appointed to the staff of the Mayo Clinic in 1928 and continued as such until October 1, 1952, when he retired. At that time he was professor of medicine in the Mayo Graduate School of Medicine.

Roy Smith was known to his intimates as

Continued



The human spine is not engineered f prolonged sitting at desks, pianos, typ writers and drafting boards. The stress set up by the heavy, forward-tilted hea and trunk, balanced precariously on a insufficient base, result in strain of th dorsal musculature, particularly at th low lumbar level.

The unusual muscle-relaxant and ana gesic properties of 'Soma' make it esp cially useful in the treatment of low bac sprains and strains. 'Soma' is wide prescribed ☐ **to relieve pain** ☐ **to rela muscles** ☐ **to restore mobility.**

Indications: 'Soma' is useful for management muscle spasm, pain, and stiffness in a variety inflammatory, traumatic, and degenerative musc loskeletal conditions. It also may act to normali motor activity in certain neurologic disturbance

Contraindications: Allergic or idiosyncratic rea tions to carisoprodol.

Precautions: 'Soma', like other central nervo system depressants, should be used with cauti in patients with known propensity for taking e cessive quantities of drugs and in patients wi known sensitivity to compounds of similar chem cal structure, e.g., meprobamate.

Side Effects: The only side effect reported with a frequency is sleepiness, usually on higher tha recommended doses. An occasional patient m not tolerate carisoprodol because of an individu reaction, such as a sensation of weakness. Oth rarely observed reactions have included dizzines ataxia, tremor, agitation, irritability, headache, i crease in eosinophil count, flushing of face, a gastrointestinal symptoms.

One instance each of pancytopenia and leuk penia, occurring when carisoprodol was admi istered with other drugs, has been reported, as h an instance of fixed drug eruption with carisoprod and subsequent cross reaction to meprobamat Rare allergic reactions, usually mild, have includ one case each of anaphylactoid reaction with mi shock and angioneurotic edema with respirato difficulty, both reversed with appropriate therap In cases of allergic or hypersensitivity reactior carisoprodol should be discontinued and approp ate therapy initiated. Suicidal attempts may pr duce coma and/or mild shock and respirato depression.

Dosage: Usual adult dose is one 350 mg. tabl three times daily and at bedtime.

Supplied: Two Strengths: 350 mg. white table and 250 mg. orange, two-piece capsules.

Before prescribing, consult package circular.

a fellow of sharp wit and abundant humor which, however, were invariably cloaked beneath the impassive countenance of an upright deacon. His expressionless face, at a moment of some pungent jest or sally, made his japery the more effective because it always took the recipient by surprise. Like Austin Davis, he was the accomplished internist, never swayed by the vagaries of the latest therapeutic enthusiasm, properly suspicious of the virtues of the newest curative agents introduced with much fanfare and sounding brass, penetrating in his diagnostic acumen and admirable in his ministrations. It is characteristic of his sound spirit of inquiry that his master's thesis of 1928, on the relation of the weight of the heart to the body and to age, has come to be a widely used guide to the weight of the normal heart. In 1953 Roy Smith became the publisher of an ancient pre-Civil War weekly newspaper, *The Mantorville Express,* where, for 52 issues, both his irrepressible wit and his innate common sense were unmistakably evident in always judicious measure. Since his retirement he has continued to live in Rochester.

BE A MYTH-MONGER #1

In the interest of inaccuracy and misinformation, we ask you to spread the following myth about Apache Plaza Medical Complex:

APACHE PLAZA MEDICAL COMPLEX IS TOO EXPENSIVE.

To be completely fair, some doctors think that's *not* a myth. For half the cost they can rent space above a beer joint in a run-down neighborhood. But, for the doctor who buys top-flight equipment, hires first-rate help, and avoids buying used cars because he doesn't want to take on someone else's problems . . . for that doctor, Apache Plaza Medical Complex makes sense. And it isn't expensive. It's just first class.

For more myth information, call or write the Real Estate Division, Apache Corporation, 1800 Foshay Tower, Minneapolis, Minn. 55402. Telephone: (612) 339-7781.

APACHE PLAZA MEDICAL COMPLEX

Stinson Boulevard at 40th Ave., N.E.

BE A MYTH-MONGER #2

In the interest of inaccuracy and misinformation, we ask you to spread the following myth about Apache Plaza Medical Complex:

YOUR PATIENTS WON'T FOLLOW YOU TO A NEW MEDICAL BUILDING NEAR A SHOPPING CENTER.

Funny. That's what people told us when we built Apache Plaza in the first place. "People won't come all the way out here to shop." But they do—some from the other side of Minneapolis. Patients will follow the *good* doctor—wherever he goes.

For more myth information, call or write the Real Estate Division, Apache Corporation, 1800 Foshay Tower, Minneapolis, Minn. 55402. Telephone: (612) 339-7781.

APACHE PLAZA MEDICAL COMPLEX

Stinson Boulevard at 40th Ave., N.E.
St. Anthony Village, Minnesota 55421

My dear Alice:

I just came upon a poem that I think is apropos that a father should send to his daughter who has just started college. I hope you not only enjoy reading the poem but that you take it to heart. I send this poem to you and finish the letter using the three greatest words in the English language.

I Love You, (Signed Father)

Lines to a Daughter

by Agnes Rogers

One of the things that you really should know
Is when to say "yes," and when to say "no."
It's terribly, terribly risky to guess
At when to say "no" and when to say "yes."
Girls who are slaving for Woolworth and Kress
Lament for the day when they might have said "yes,"
Others are crying at night apropos
Of moments when clearly they should have said "no."
There aren't any textbooks, there aren't many rules,
The subject's neglected in orthodox schools.
Experience helps, but you seldom remember
Your April mistakes by the first of November.
You can't be consistent; there's often a reason
For changing your mind with a change in the season.
You may be quite right in accepting at seven
Suggestions you'd better refuse at eleven.
Perhaps you'll consider these tentative hints:
"No" to a dirndl of highly glazed chintz,
"Yes" to the bashful young man at the dance,
"No" to the man who's been living in France,
"Yes" to a walk in the park in the rain,
"Yes" if he asks for a chance to explain,
"No" to all slacks unless you're too thin,
"No" to that impulse to telephone him,
"Yes" to a baby, and "no" to a bore,
"No" if you're asked if you've heard it before,
"Yes" to the friend when she says, "Don't you think
Rabbit is just as becoming as mink?"
"Yes" to a Saturday, "no" to a Monday,
"Yes" to a salad and "no" to a sundae,
"No" to a wastrel and "yes" to a ranger,
"No" to a toady, and "yes" to a stranger
(That is, providing you use some discretion),
"No" to three cocktails in rapid succession,
"No" to magenta and chocolate brown,
"Yes" to a whisper and "no" to a frown,
"No" if he's misunderstood by his wife,
"Yes" if you want it the rest of your life.
Remember, my darling, careers and caresses
Depend on our choices of "noes" and of "yesses."

the mid-rift!

Our population's bursting at the seams.

It's eat. Eat. Eat.

And then diet. Diet. Diet.

With the latest No-calorie.
No carbohydrate. No-vitamin. No exercise.
400-hour Kamikaze Plan!

When it's over, it's eat, eat, eat again.

As a professional you can help wrest some sense from this nonsense: first, by cautioning against skipping meals, and second by pointing the way to realistic weight control through nourishing meals every day. Day after day.

Naturally, balanced diets and nourishing, palatable dairy foods go together; they always have.

Project Weight Watch has been initiated to assist you. Its scope is nationwide, its purpose is to focus professional attention on the problem.

To help you translate your concern to your patients, a portfolio of materials is available. Send for it. Help stamp out needless waist.

The Editor's Soliloquy

Obfuscuity

"If language is not correct, then what is said is not what is meant; if what is said is not what is meant, then what ought to be remains undone." Confucius

Obscurantism diffuses like a fog through medical writing. The message of this essay is that obscurity, when properly used, can lead to publication. The obscurantist's goal is clear — to produce the greatest number of papers from the minimal amount of data using the maximal number of words.

The code is straightforward: to say nothing well and not to stop when you have said it. The obscurist believes that clarity is degrading, that blunt statements are impolite, and that vagueness is safer than precision. Although the code is simple, the gambits require definition. There are three basic ploys for physicians who aspire to turbid, but publishable, prose.

Windfoggery is the bedrock of all abstruseness. Wind and fog do not coexist in nature but merge murkily on the printed page. Give the reader a low-fact diet with a high-jargon content. Sprinkle with polysyllabic words and scramble the syntax. For example, if you doubt a predecessor's methods, don't say: "Jones' methods are questionable." Raise the fog index and the wind velocity by saying: "The quantitative parameters assayed by Jones were analyzed and appeared, according to our intrepretations, to demonstrate significant fluctuations which seem to vacillate diurnally."

The *Humble Hedge* is a gambit whereby you qualify your meaning into nothingness while appearing to be objective. Always convey doubts about your statements. Arrange a retreat from clarity with hedge verbs like *indicate, suggest, appear to be, may,* and *might.* Withdraw with these nouns: *speculation, conjecture, theory,* and *hypothesis.* Hedges can be classified as first, second, and third order or as single, double, and triple-barrelled. A fourth order, the quadribarrelled, is clumsy and should be avoided. A fifth-order hedge, such as "Speculation about etiological factors might possibly suggest that previous investigators may have been wrong," is excessive and very poor form. The sentence could be reduced to a third-order hedge with only slight loss of ambiguity.

Word Wedging is forcing impressive words into sentences where they don't belong. The careful wedger selects his tools meticulously. He prefers abstract terms with scientific or literary overtones, e.g., armamentarium, biome, congeners, continuum, dynamic, esoteric, forme fruste, harvest, kinetics methodology, modality, oncogenesis, parameter, and sophisticated. The following example of artful wedging is from an article in a well known medical journal: "Substances which are immunologically foreign are composed of *autochthonous* materials; these are not diagnostic, but with progressive increase, as seen by serial samples, in association with other suspicious *parameters,* the electrophoretic pattern may become significant as a *predictor.*" Observe the clever mingling of windfoggery, hedging, and wedging — all combining to produce a hieroglyphic obfuscuity.

to help relieve pain in common anorectal disorders

"non-caine" Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form...both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.

DIOTHANE
OINTMENT
Soothing, Temporary Relief of Hemorrhoidal Pain, Rectal Itching
CHILD
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

MINNESOTA MEDICINE
HONOR AWARD

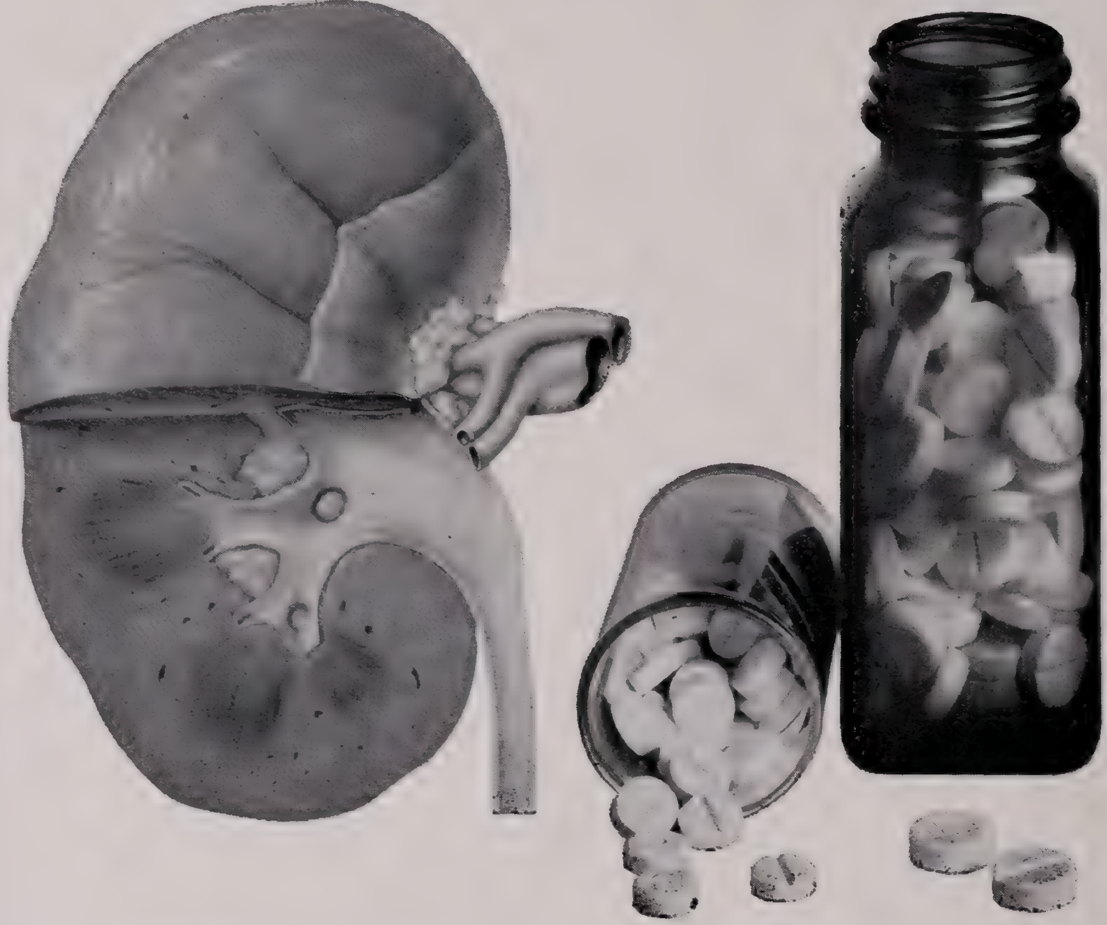
Minnesota Medicine Medical Writing Awards, 1966

It is the pleasure of the Board of Editors to announce the winners of the fifth annual Minnesota Medicine Medical Writing Awards chosen from articles published in MINNESOTA MEDICINE during the year of 1965.

The first place plaque is to be awarded to Dr. Donald M. Yamaguchi of Gardens, California (formerly at the Mayo Clinic in Rochester), Dr. Paul R. Lipscomb and Dr. Edward H. Soule of the Mayo Clinic in Rochester. Their article "Carpal Tunnel Syndrome" appeared in the January issue of MINNESOTA MEDICINE, page 22. The presentation will take place during the annual meeting of the Minnesota State Medical Association in St. Paul at the New Members, County Officers and Delegates Dinner on Sunday, May 15.

Certificates for excellence in medical writing will be awarded to the authors listed on the next page whose article was felt to be particularly outstanding by the Board of Editors.

at Merck Sharp & Dohme...



understanding... precedes development

The development of chlorothiazide and probenecid were events of major importance, but perhaps even more important for the future was the Renal Research Program by which they were developed. When Merck Sharp & Dohme organized this program in 1943, it was expressing in action some of its basic beliefs about research:

- Many problems connected with renal structure and function were still undefined or unsolved. The Renal Research Program would begin its basic research in some of these problem areas.
- From knowledge thus acquired might come clues to the development of new therapeutic agents of significant value to the physician.

For example, the Renal Research Program put fifteen years into this search before chlorothiazide became available. But because these years had first led to a greater understanding of basic problems, the desired criteria for chlorothiazide existed before the drug was developed.

Along with other research teams at Merck Sharp & Dohme, the Renal Research Program continues to add new understanding of basic problems—understanding which will lead to important new therapeutic agents.

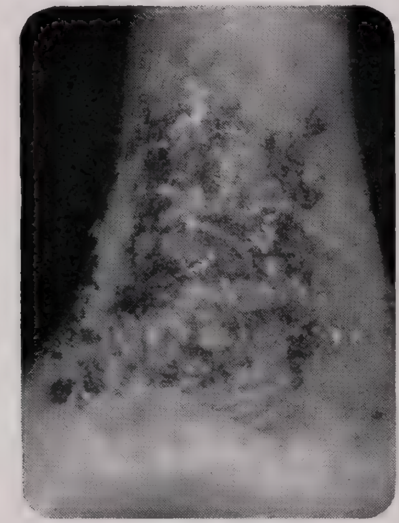
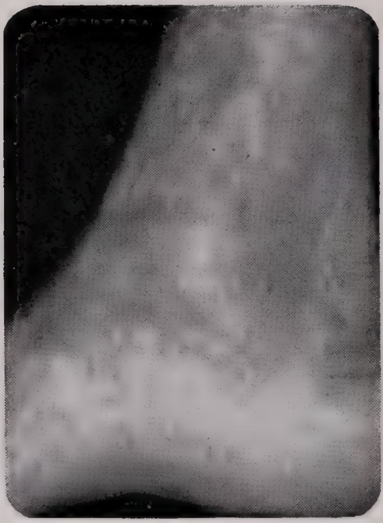
eczema: scourge of childhood



R. R., Age 11—Before treatment—
atopic eczema of long standing



After treatment—with ARISTOCORT
Topical Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of childhood eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive nonpermeable dressings, may result in systemic absorption. Appropriate precautions should be taken. When occlusive nonpermeable dressings are used, miliaria, folliculitis and pyodermas will sometimes develop. Localized atrophy and striae have been reported with the use of steroids by the occlusive technique. When occlusive nonpermeable dressings are used, the physician should be aware of the hazards of suffocation and flammability. The safety of use on pregnant patients has not been firmly established. Thus, do not use in large amounts or for long periods of time on pregnant patients.

Packages: Tubes of 5 Gm. and 15 Gm.; ½ lb. jar.

Fifty Years of Honorable Service in Minnesota

The presentation of certificates and pins to Minnesota physicians who have engaged in the practice of medicine for 50 years has become an impressive highlight of each Annual Meeting. According to custom the presentations are made during the course of the Annual Banquet. Few who have witnessed these ceremonies soon forget the setting of such an occasion at which these colleagues with a half century of medical practice to their credit so alertly respond to the roll call.

The custom of honoring Minnesota physicians who have served their patients and communities for a half century was established in 1942. Forty-one physicians were honored at the first ceremony. This group also included those who had passed the 50-year mark prior to 1942.

To be eligible for this award a doctor must have spent the majority of his 50 years practicing medicine in Minnesota.

In 1966 ten doctors were added to the membership rolls of the Fifty Year Club.

Henry E. Binet, M.D.

Dr. Binet practiced medicine almost thirty years in the Range area before his retirement in 1946. He was born at Marquette, Michigan, in July of 1889, and obtained his preliminary education at Marquette, Michigan, and Coleraine, Minnesota. His medical degree was obtained at Northwestern University Medical School in 1916. Immediately following his graduation he returned to Grand Rapids and began his practice in association with Dr. M. N. Hursch. He is a veteran of World War I, where he served in the Army Medical Corps.

First president of the medical society in the Range area, Dr. Binet is a fellow of the American College of surgeons and numerous medical associations. At the present, he is enjoying a well deserved retirement in Grand Rapids.

Bottolf T. Bottolfson, M.D.

Dr. Bottolfson began his practice in Halstad, Minnesota, prior to World War I, but then entered the Medical Corps as a first lieutenant. On his return from the Army he practiced with Dr. A. J. Hageu for three years and thereafter continued in independent private practice at Moorhead, Minnesota, where he has served two terms as mayor and is currently one of the members of their Charter Commission.

Dr. Bottolfson had a wide interest in all fields of medicine and has taken postgraduate courses in Urology, Eye, Ear, Nose and Throat, Neurology and Bronchoscopy in order to keep himself abreast of advancing medical problems.

He is a member of the American College of Surgeons, International College of Surgeons, American Urological Society, North Central Branch of the American Urological Society, Pan American Congress of Ophthalmology and the North Dakota Academy of Ophthalmology and Otolaryngology.

Austin C. Davis, M.D.

Dr. Davis was born at Libertyville, Iowa, on August 12, 1891. His father and one brother were physicians. One of his sons is also a physician.

Dr. Davis finished his elementary education and first two years of college at Parsons College, Fairfield, Iowa, and completed his third year of Liberal Arts and first two years of Medicine at the University of Iowa, from which he received the degree of A.B. in 1913. From 1913-1914 he taught bacteriology at Parsons College and was graduated from Medical School at the University of Iowa in June, 1916. An intern in Internal Medicine during 1916-1917, Dr. Davis was a hospital chemist during the following year.

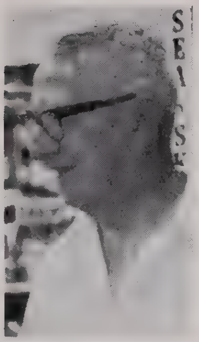
Then he joined the United States Army Medical Corps as a first lieutenant, serving until September 1919. Following military service he returned to the University of Iowa where he served as assistant until July 1, 1923, when he was appointed to the staff of the Mayo Clinic as first assistant, remaining there until his retirement October 1, 1956. His service was in Internal Medicine with particular attention to Endocrinology and was also assistant professor in the Graduate School.

Dr. Davis was a diplomate of the American Board of Internal Medicine, a Fellow of the American Medical Association and a Fellow of the American College of Medicine. He was also a member of Nu Sigma Nu, Sigma Xi, AOA and AFI.

Dr. McClanahan has practiced medicine in White Bear Lake since 1921. He was born in Kirkwood, Illinois, in 1891, and obtained his preliminary education at Monmouth College in Monmouth, Illinois. In 1916 he received his medical degree from Northwestern University Medical School and was licensed that same year in Illinois.

A veteran of World War I, serving in the medical corps, Dr. McClanahan came to Minnesota and was licensed to practice medicine in 1919.

He has served as chief-of-staff at St. John's Hospital in St. Paul and is a member of many national and state medical associations and societies.



Thomas S. McClanahan, M.D.

Dr. McDaniel was born in Bartow, Georgia, on July 14, 1894. He graduated from Emory University, interned at Denver and Rio Grande Hospital in Salida, Colorado. For a period of time he practiced in Virginia, Minnesota, then in Brunswick, Georgia, for about 13 years, and finally returned to Lakeville, Minnesota, where he has practiced up to the present time.

He has one daughter who is director of a three-county Regional Library in Elko, Nevada.

Samuel P. McDaniel, M.D.

Dr. McIntyre was born July 13, 1890, in Davenport, Iowa. After finishing his undergraduate education in Iowa and graduating from Harvard Medical School in 1916, he returned to Iowa to spend his internship. In the First World War he served in the American Expeditionary Force for 15 months and then did postgraduate work at the University of Toulouse, France. He subsequently returned to Minnesota and has practiced in Round Lake and Owatonna to the present date. He was twice Chief of Staff of the Owatonna City Hospital. He continues to do a limited practice up to this moment.

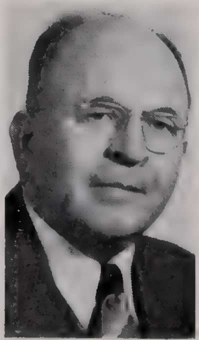
John A. McIntyre, M.D.

Dr. McKinlay was born in Wichita, Kansas, but spent most of his boyhood years in Newkirk, Oklahoma.

After graduation from the University of Kansas School of Medicine, he received his license to practice in the state of Kansas in 1916. Following an internship in Montreal General Hospital, a year of residency in Pathology at the New Haven Hospital, Yale University, service in the U. S. Army and a year of residency at the University of Minnesota Hospital, he started practice in Minneapolis in Internal Medicine in the summer of 1921.

Dr. McKinlay has been a staff member of Asbury, Northwestern, University and General Hospitals and served for a period of time on the Student Health Service, attaining the rank of Associate Clinical Professor of Medicine.

He was a director and later President of the Minnesota Blue Shield for several years and was on the Board of the Minnesota Tuberculosis and Health Association, serving later as President. He has been a member of numerous professional societies including the American College of Physicians. American College of Chest Physicians, Central Society of Clinical Research, Minnesota Pathological Society and the Minneapolis and Minnesota Academies of Medicine.



Chauncey A. McKinlay, M.D.

Continued

John R. McNutt, M.D.

Dr. McNutt was born in New Bethlehem, Pennsylvania, on May 8, 1889. After obtaining his preliminary education at Clarion State Normal High School in New Bethlehem, he received his medical degree from the University of Michigan Medical School in 1916. That same year Dr. McNutt was licensed in Michigan.

In 1918 he went to Two Harbors and practiced there until 1928, specializing in radiology from 1928 through 1930. Shortly afterward he went to Duluth and specialized in radiology, becoming Chief-of-Staff at St. Mary's Hospital in Superior. Later, in 1933, when it was first built, Dr. McNutt opened his office in the Medical Arts Building.

Dr. McNutt was in the first class to be certified in 1935 as a diplomate of the American Board of Radiology and is a fellow of the American College of Radiology. He is also a member of the Radiological Society of North America and American Roentgen Ray Society and a past president of the Minnesota Radiological Society. At one time Dr. McNutt was secretary-treasurer of the Inter-urban County Medical Society.

He is married to Elsie Gerlach, and they have four children.

Joe M. Neal, M.D.

As told by the Department of Insurance News Letter, **Dr. Neal** is an expert story teller, a fine friend and an all-around good fellow. He was a "dean" among insurance personnel, having served in the Veterans Administration in the medical field for more than forty years.

Dr. Neal was born in Gallipolis, Ohio, shortly before the turn of the century. While growing up, he spent his time alternating between his father's drug store and steamboats on the Ohio River. Finally graduating from the College of Pharmacy of Ohio State University, he went into the field of medicine.

He came to Minneapolis in 1916 and served an internship at the Minneapolis General Hospital, and for a period of time he was City Physician and Acting Superintendent.

In 1918 he served in the Army Medical Corps and since then has been interested in the Veterans Administration and their medical problems, serving as a medical consultant in the Disability Insurance Claims Division. Dr. Neal has two children and five grandchildren. He is active in the Masonic Order, the Shrine and the American Legion. Although he is not in practice, he continues to remain active and energetic.

Harry L. Smith, M.D.

Dr. Smith, a specialist in diseases of the heart at the Mayo Clinic from 1928 to 1952, and emeritus professor of medicine in the Mayo Graduate School of Medicine, University of Minnesota at Rochester, was born on September 3, 1887, in Fairport, Missouri. He took the degree of doctor of medicine in 1916 from the State University of Iowa. After an internship in Vancouver, British Columbia, Dr. Smith entered the army in 1917 as a first lieutenant in the Medical Corps. In 1917 he became a diplomate of the National Board of Medical Examiners. After his discharge in 1919, he began the private practice of medicine in Walnut, Iowa, where he remained from 1920 to 1925.

Dr. Smith came to Rochester in June 1925 as a fellow in medicine in the Mayo Graduate School of Medicine. On January 1, 1928, he was appointed to the staff of the Mayo Clinic and in the same year received the degree of master of science in medicine from the University of Minnesota.

Dr. Smith was also professor of medicine in the Mayo Graduate School of Medicine, University of Minnesota at Rochester. He became head of a section of medicine in the Mayo Clinic on July 1, 1945, and a senior consultant in medicine on January 1, 1951. He retired from active practice on October 1, 1952.

In 1936 Dr. Smith was certified as a specialist in cardiovascular diseases by the American Board of Internal Medicine, Inc. He was a fellow of the American College of Physicians, a former president of the Zumbro Valley Medical Society, and a member of the Minnesota State Medical Association, the Minnesota Society of Internal Medicine, the Minnesota Heart Association, the American Heart Association, the Society of the Sigma Xi, the Central Society for Clinical Research, the Alpha Omega Alpha medical honor society and the Nu Sigma Nu professional medical fraternity. During World War II he held the grade of lieutenant colonel in the State Guard in Minnesota.

Curbstone Consultation

QUESTION: My ulcer patient has positive stool guiac tests. His hemoglobin dropped within an 8-hour period from 13 to 12 gram %. Is this significant?

ANSWER: Physiologic variation plus the standard error in hemoglobin determination could account for as much as one gram % difference in hemoglobin level, and therefore, its clinical significance should be interpreted with utmost caution.

QUESTION: What chemical test can I order to help follow the status of my patient with diagnosed hypothyroidism who is being treated with thyroid extract?

ANSWER: The PBI test can be used in this situation to approximate the serum thyroxine level. Most of the PBI measured will be the exogenous thyroid extract. If the patient is being treated with Tri-iodothyronine (Cytomel) the PBI cannot be used, as it will be low.

QUESTION: What is the best screening test for diabetes?

ANSWER: Two-hour post-prandial blood sugar, utilizing a meal containing 100 gm. of carbohydrate.

QUESTION: How soon is the urinary immunologic pregnancy test positive after the last menstrual period?

ANSWER: The excretion of chorionic gonadotropin is at an optimum level from six to 17 weeks after the last menstrual period. A negative result on a specimen obtained prior to six weeks from beginning of last menstrual period should be repeated with a specimen collected after the six weeks.

Helps keep arthritic patients active

P-B-SAL-C is a dependable, effective salicylate formula for relief of pain due to rheumatoid arthritis, bursitis and fibrositis.

Its formula consists of a combination of sodium salicylate, para-aminobenzoic acid and ascorbic acid. This special combination provides higher, longer-lasting analgesic levels compared with salicylates alone. Each P-B-SAL-C Tablet is enteric coated to delay disintegration until it reaches the small intestine.

P-B-SAL-C, low in cost to your arthritic patients, will help keep them active. Other P-B-SAL-C formulas available:

1. P-B-SAL-C with Colchicine
2. P-B-SAL-C with Esoprine
3. P-B-SAL-C Sodium Free
4. P-B-SAL-C with Prednisolene (Sodium Free)

For complete information and samples, write to Dept. 00-105

FORMULA

Each enteric-coated P-B-SAL-C Tablet contains sodium salicylate 0.3 Gm., para-aminobenzoic acid 0.3 Gm., ascorbic acid 50.0 mg.

CONTRAINDICATIONS

Renal damage, salicylate sensitivity or in conjunction with sulfonamide therapy.

DOSAGE

Take 2 tablets four or more times daily.

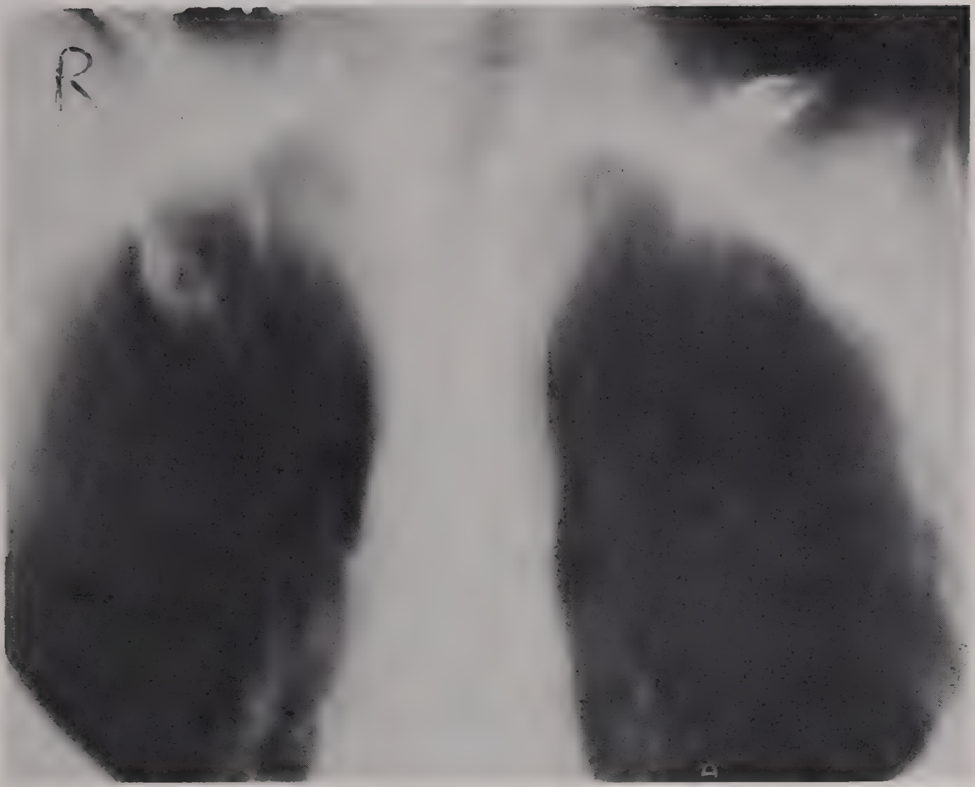
The Viewing Box



This 43-year-old unemployed white male gave a history of chronic cough with production of white sputum, weight loss, and fatigue for the past year. The symptoms became worse during the last three months, together with the appearance of low-grade fever and night sweats. He was a heavy smoker. There was no family history of tuberculosis. Skin tests were negative to old tuberculin 1:1000, histoplasmin, and coccidioidin.

The plain roentgenogram and the planigram (Figure 1) of the chest showed bilateral apical lesions: a nodular density with central cavitation on the right, and a small, thin-walled cavity on the left side.

Among the diagnoses considered were:

1. Tuberculosis.
2. Coccidioidymycosis.
3. Metastatic carcinoma.
4. "Atypical" mycobacterial disease.
5. Cavitating infarcts or embolic abscesses.

What is your diagnosis? (See next page.)

Diagnosis: Pulmonary disease caused by atypical mycobacterium (mycobacteriosis), group III (Battey bacillus).

The "atypical" or "unclassified" mycobacteria may be separated into four groups, according to Runyon:

Group I. Photochromogens (M. kansasii and M. balnei).
Group II. Scotochromogens (M. scrofulaceous).
Group III. Nonphotochromogens, including the Battey bacillus.
Group IV. Rapid growers, including M. fortuitum.

Pulmonary infections caused by the Battey bacillus are most common in the southern and southeastern United States, especially in rural areas of southern Georgia. In these regions the organism has been isolated from the soil and from the throats of healthy persons. The natural habitats of the organisms and the route of infection need further clarification. The disease is generally considered noncommunicable, because conjugal and familial cases are very rare. At the Glen Lake State Sanatorium, we have seen eight cases of clinical disease caused by the Battey bacillus in the past ten years.

The most common symptoms are cough, expectoration, weight loss, weakness and dyspnea. Less frequently noted are hemoptysis, chest pain, and low-grade fever. The diagnosis depends on demonstration of the bacillus by cultures from sputum or resected and biopsy materials. Single isolations with scanty growth of organisms on sputum cultures are likely to be contaminants. However, repeated growth from sputum or resected specimens are significant. Associated or predisposing illness may be emphysema, silicosis, or bronchiectasis. A skin test antigen, PPD-B (purified protein derivative of the Battey strain mycobacterium), is available as an aid in diagnosis.

The roentgen findings of the present case are supposed to be suggestive of mycobacteriosis: (1) large areas of cavitation in relation to the total extent of pulmonary involvement, (2) thin-walled cavity with lack of pericavitary inflammation, and (3) absence of satellite nodules, hilar elevation, bronchogenic spread, and pleural effusion. More often than not, however, these features are absent, and the roentgen picture is indistinguishable from that of pulmonary tuberculosis. Even miliary lesions and large pleural effusions have been encountered.

Treatment is both medical and surgical. Medical treatment is similar to that for tuberculosis, including prolonged multiple drug therapy with streptomycin, isoniazid, para-amino-salicylic acid, and other agents. Resection is strongly indicated if the patient is a suitable candidate for surgery. Early resection and chemotherapy will convert about 75% of the cases to an active status with negative bacteriology, while only 25-30% will satisfactorily respond to medical treatment alone.

Fracture–Trauma Conference

Arteriovenous Fistula Following a Cervical Stab Wound

IT IS FORTUNATE that deep wounds of the neck are relatively uncommon. A penetrating wound violating the central core of the cervical area is likely to injure one or more of the important vascular, digestive, or respiratory structures therein. Both early and late complications occur with alarming frequency and the over-all mortality may be as high as 11%.[1]

A detailed exploration of cervical wounds requires endotracheal anesthesia and optimum operating room conditions. These may be difficult to obtain at night when many of these injuries occur, and unless a life-threatening condition exists (i. e., hemorrhage or airway obstruction) there seems to be a general tendency for surgeons to treat these wounds conservatively by simply irrigating the points of entry and exit, providing drainage where indicated, and achieving skin closure. This type of treatment will be adequate in certain instances; however, experience has shown that unless an extensive exploration of the wound is accomplished on admission, an unnecessary and disturbing number of delayed or late complications will occur.

An interesting late complication of any penetrating wound is the development of a traumatic arteriovenous fistula. William Hunter first described this formation and Holman established clearly the presenting signs and symptoms.[2] Experience during the Korean War[3] demonstrated the superiority of early reconstruction of at least the arterial channel over the previously recommended quadruple ligation technique. Of patients with carotid to internal jugular vein fistulas, 70% will develop a complication if the condition is allowed to persist for three years.[4]

The following case history illustrates the development of a traumatic arteriovenous fistula and, as suggested by the foregoing discussion, it was felt desirable to correct the defect at the earliest convenient time.

Case History

A 22-year-old male was stabbed in the right chest and right lower cervical area on June 24, 1963. He was admitted to Hennepin County General Hospital in shock; how-

Continued

ever, with blood replacement his vital signs stabilized, and he was taken to the operating room for definitive care of his wounds. Both wounds were copiously irrigated, and when no further bleeding was observed, they were closed. X-rays of the chest revealed no evidence of continued hemorrhage. He was subsequently discharged but was readmitted on July 7, 1963, two weeks after his original injury, because of further bleeding from his chest wound. He was prepared for surgery, a formal exploration of his chest wound was performed by open thoracotomy, and when a severed internal mammary artery was found to be the offending vessel, it was appropriately ligated.

During the second operation the anesthesiologist discovered that a palpable thrill and audible bruit were present over the healed cervical stab wound. On July 17, 1963, a retrograde aortogram was performed, revealing a fistula to be present between the right common carotid artery and the internal jugular vein with a false aneurysm.

The patient was again prepared for surgery. Local anesthesia was utilized early in the procedure, and it was found that a three-and-one-half minute occlusion of the common carotid artery produced no neurological symptoms or signs. General anesthesia was then initiated, and the carotid artery and jugular vein proximal and distal to the fistula were secured with twill tapes. The vessels were then occluded, the fistula taken down, and the false aneurysm resected. In order to prevent constriction of the lumen, a teflon gusset was used to close the rent in the artery. Flow was allowed through the carotid, and the vein was repaired with a running suture of 5-0 silk. The carotid artery had been occluded for thirty-four minutes, and there were no neurological sequelae. The patient's recovery was uneventful.

Discussion

Repair of an open bleeding vessel or of a severely traumatized vessel may be readily accomplished with the generous exposure required for an extensive exploration as advocated. If this had been performed in the case described, the arteriovenous fistula probably would not have developed. It was fortunate that a secondary hemorrhage did not occur, because the massive swelling in the neck accompanying this complication is terrifying to behold and extremely dangerous.

Esophageal wounds as well as blood-vessel wounds may not produce dramatic clinical signs or symptoms in the early post-injury period, but the resultant morbidity and mortality could likely be eliminated if the defect were detected and subsequently repaired during a more thorough initial exploration of the wound.

Expectant treatment of penetrating cervical wounds is not unlike such treatment of similar wounds of the abdomen — fraught with danger. The best course of treatment would appear to be for the surgeon to alert the operating room for a major neck exploration and to prepare himself to properly reconstruct the damaged respiratory, digestive, vascular, and neural structures he may encounter as he systematically performs a search of the wound tract.

Tumor Conference

An Unusual Breast Cancer

Squamous-Cell Carcinoma Arising in a Tattoo

The usual skin malignancy has little to distinguish it. A recent case had the interesting features of prolonged history, peculiar location, exotic surrounding features, as well as possible involvement of tattoo pigments in the etiology of the squamous-cell carcinoma.

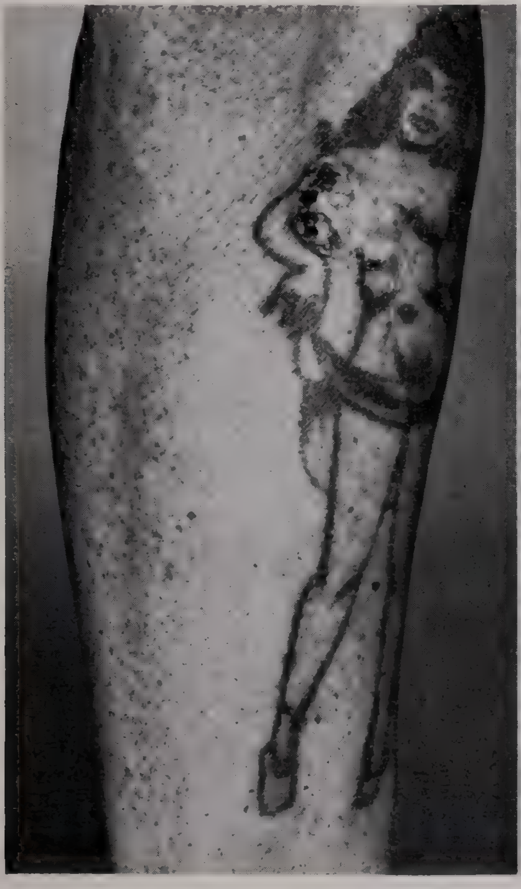

Fig. 1 — A photo of the lesion on the forearm.

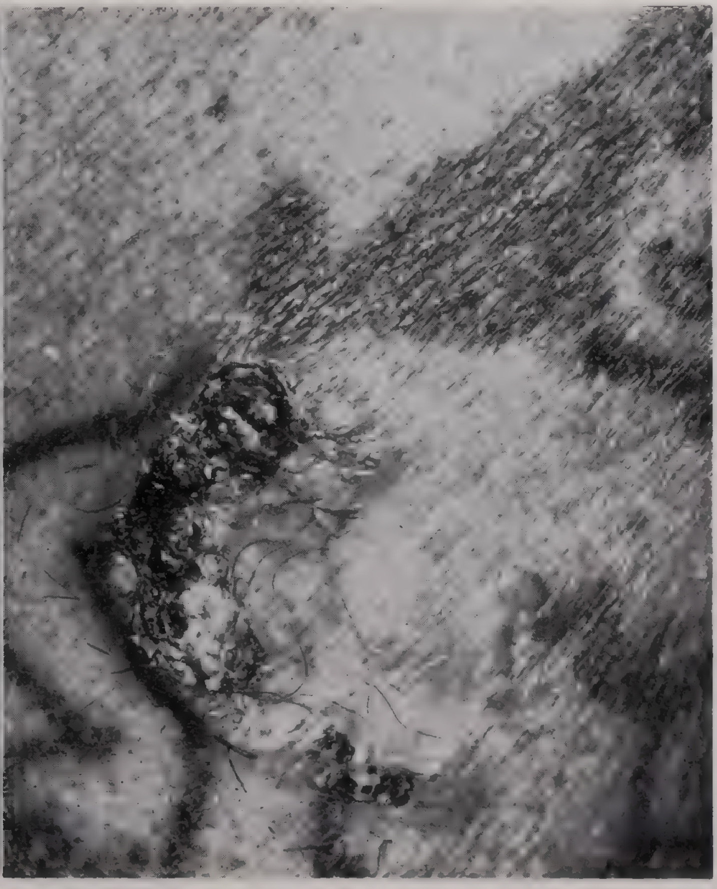

Fig. 2 — A closer view of the lesion showing peripheral spreading from a scarred area.

Continued

Case History

The patient was a 40-year-old active-duty sailor who was seen at our hospital for an infected, raised, scarred lesion in a tattoo on his right forearm. Twenty-one years previously a female figure had been tattooed in blue line on the right forearm. Red pigment had been used for embellishments in the areas of lips, nipples and groin. Ten years ago he noted an itching, scaling, indurated lesion in the area of the red pigment on the figure's nipple. This lesion persisted, essentially unchanged, until four years ago when he scratched the area while working with rose bushes. The area of the tattoo became acutely infected and inflamed. The patient stated that since the acute infection subsided there had been a constantly enlarging, chronically inflamed, itching, raised lesion in the area of the breast of the tattoo. Two years ago he was treated elsewhere with a two-month course of Griseofulvin, without effect. Through the years he had spent much time in the sun.

The patient was a healthy, red-headed, fair-skinned man. The ulcerated lesion was present on the right forearm in the right breast of the tattoo. This is illustrated in Figures 1 and 2.

A biopsy was interpreted as showing squamous-cell carcinoma. Cultures grew only DNA positive staphlococcus. One soft node, (1 x 2 cm.) was felt in the anterior axilla. The patient was admitted to the Plastic Surgery Service and had a wide excision of the lesion. The defect was covered with a split-thickness skin graft. A section from the surgical specimen is shown in Figure 3. Tattoo pigment is easily identified within the tumor (Figure 4). At the time of discharge from the hospital and on two subsequent clinic visits, no axillary nodes could be felt.

Comments

The history of this lesion suggests that there was initially a chronic dermatitis in the area of the red portions of the tattoo with the subsequent development of a squamous-cell carcinoma.

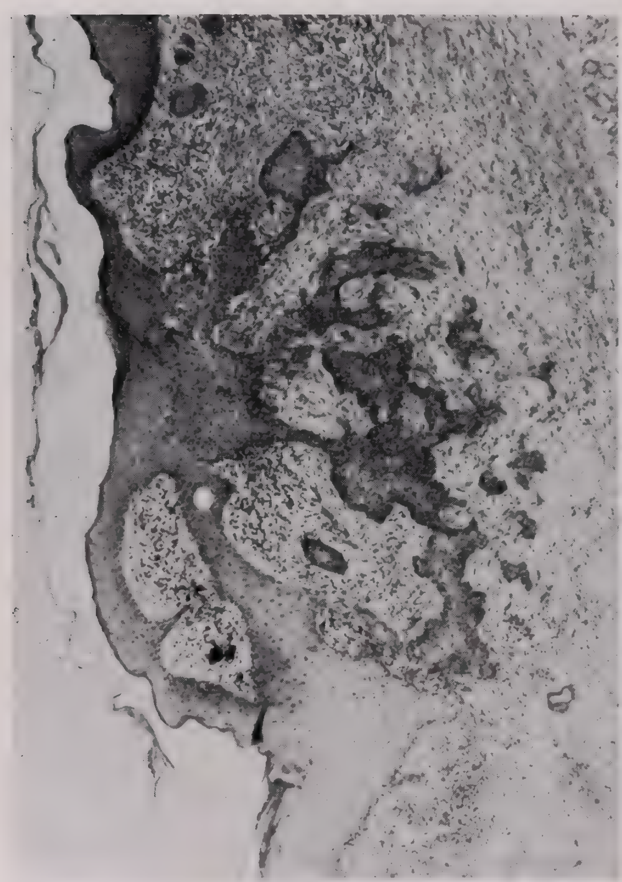

Fig. 3 — A photomicrograph of an area of the tumor containing tattoo pigment.

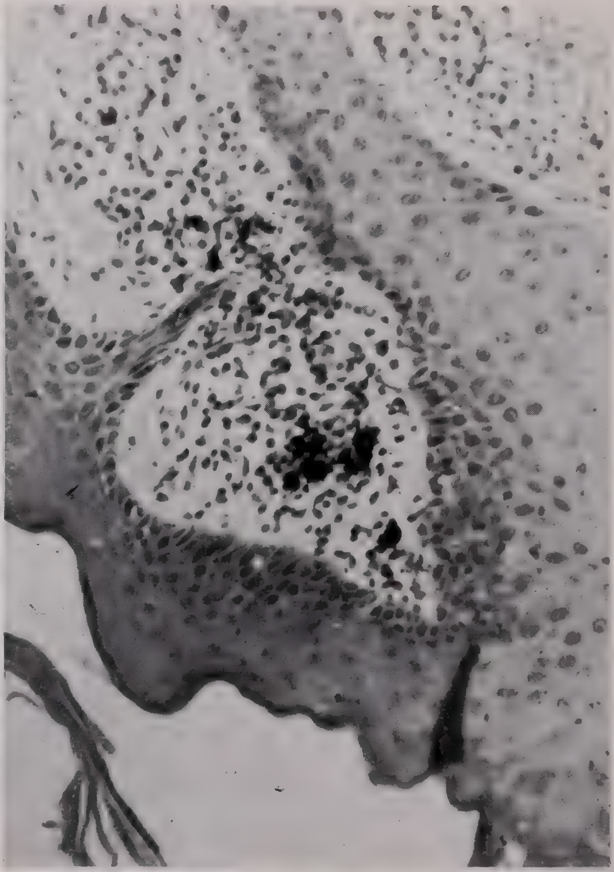

Fig. 4 — A high-powered view of the same area with characteristic tattoo pigments in the tumor area.

The usual red pigment used in tattooing is cinnabar (mercuric sulfide). The other red pigments used are cadmium red (cadmium selenide) and sienna or Mars red (ferric hydrate). Of the many complications of tattooing,[1] one of the more common is a local dermatitis caused by reaction to, or sensitization by, mercury.[2-4] The dermatitis can involve any or all areas of cinnabar tattoo.

It is interesting to speculate as to whether the tattooing agents might have acted as a primary carcinogen or as a co-carcinogen with ultraviolet irradiation. Among the metals, arsenic, nickel, chromium, beryllium, cobalt, selenium, and iron have all been incriminated in some circumstances as carcinogens.[5] Mercury is not included in the usual list of agents. Considering the frequency of tattooing, case reports of malignancy in tattoos are extremely rare.[1]

Sarcoma and melanoma have been found in tattoos, but we are unable to find a previous documented case of squamous-cell carcinoma arising in a tattoo. Squamous-cell carcinoma is an occasional, but well-known, consequence of a long-standing inflammatory process. It would seem more likely that the squamous-cell carcinoma in this case arose secondarily in a chronic dermatitis rather than as a primary response to tattoo pigments.

It is unfortunate that this lesion was observed over the last four years without biopsy, while being treated by several physicians.

Correction

Medicine in Wright County

In the biographical section of this history — MINNESOTA MEDICINE 45: 673, June, 1962, — a Dr. Edwin Young Clinton is listed. It has since become clear that Dr. Clinton is a ghost and should be disposed of. A thorough research failed to disclose any definite trace of him. There is very little doubt but that there was no Dr. Clinton. His initials, as well as the biographical data, are identical with those of Dr. Edwin Y. Chilton of Howard Lake, Wright County.

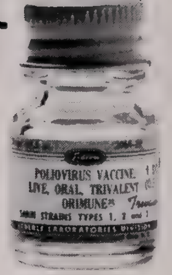
single-dose vials for convenient and economical polio immunization



ORIMUNE® TRIVALENT
POLIOVIRUS VACCINE, LIVE, ORAL SABIN STRAINS TYPES 1, 2 and 3

Fast, simple administration—and economy for the patient—make the new 0.5 cc single-dose vial of ORIMUNE Trivalent ideal for private practice. (Packaged 5 to a box with 5 sterilized disposable droppers for your convenience.)

(Also available in 2 cc and 2 drop dosage forms.)

Only 2 doses required for complete, initial immunization for patients more than a year old.

Effectiveness — may be expected to confer active immunity against all three types of poliovirus infection in at least ninety percent of susceptibles only if given at full dosage, as directed. No characteristic *side effects* have been reported. There are, however, certain *contraindications.* These are, broadly: acute illness, conditions which may adversely affect immune response, and advanced debilitated states. In these, vaccination should be postponed until after recovery.

In infants vaccination should not be commenced before the sixth week of life. Do not give to patients with viral disease, or if there is persistent diarrhea or vomiting. ORIMUNE and live virus measles vaccine should be given separately.

Dosage—initial immunization: two doses each given orally at least 8 weeks apart. (Give a third dose to infants at 10-12 months.) Booster immunization: one dose, given orally. See package literature for full directions.

Neuro-Pediatrics Conference

The Sequelae of Prematurity in a School-Age Child[*]

Dr. Charles Branthaver[**]

The child being evaluated today demonstrates some of the more subtle neurosensory deficits that may result from prematurity. These deficits may not be fully recognized until school-age when certain standards in performance identify the child as deviating from these standards. Prior to this time some suspicion of abnormality may be present which becomes more obvious as the child functions with his peer group.

We have with us representatives from the school which Gail attends in addition to the University staff involved in the evaluation of this child. From this discussion we would hope to achieve a more comprehensive understanding of Gail's performance and ways in which this can be maximally utilized. Dr. Ryan could you give us the initial history and physical findings?

Dr. Dennis Ryan[†]

Gail is a 6-year, 9-month-old white girl who was referred to the University because of a learning problem in kindergarten last year. The school wanted an evaluation of the neurologic aspects of her learning difficulties. Because of the father's antipathy toward doctors there was no referring physician.

Gail was born at the University Hospitals at 31 weeks gestation and weighed 1430 grams (3 lbs., 2 oz.). The labor was uncomplicated and there was no immediate perinatal distress. At 36 hours jaundice was noted and a bilirubin of 13.4 mg. was obtained, rising to 25 mg. at 60 hours of life. Direct and indirect Coombs were negative. The mother's blood type was A positive and Gail's O positive. She was given two exchange transfusions, one at three and the other at five days of age. Her temperature did not stabilize at higher than 97° until the fourth week of life. She did not

[*] Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatrics conferences are held weekly on Wednesdays from 1:00 to 2:00 p.m. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Charles Branthaver and Dr. Edward Defoe in Pediatrics, and Dr. Robert Soll, in Adult Neurology.

Held on Wednesday, September 8, 1965, at 1:00 p.m.

[**] Pediatric coordinator. University of Minnesota Hospitals.

[†] Student Physician, University of Minnesota Hospitals.

Continued

regain her birth weight until five weeks of age and did not attain the requisite 5½ lbs. for release from the hospital until two months of age. She was readmitted at three months with an upper respiratory infection and at 10 months with a Salmonella gastroenteritis. At the latter time the pediatric neurologist felt she had a spastic diplegia. The child was then lost to further medical follow-up until her present evaluation. Gail's developmental history is marked by sitting at six to seven months, crawling at nine months, walking by two years, tricycle riding at three to four years and dressing herself at about four to five years. She smiled at one month, spoke a very few words at 18 months and used sentences at about the age of five.

On physical examination Gail is a very thin, active girl who chatters incessantly. She was quite cooperative but tended to perseverate whenever she was "stressed." Her height and weight were below the 30th percentile for six and a half years of age. Head size was normal at 51 cm.

The rest of the physical examination was essentially normal except for the neurologic findings. There was a mild spasticity, greater on the left than on the right, and greater in the lower than the upper extremities. She had hyper-reflexia, a slight circumduction of her foot on running and was able to hop on her right foot, but couldn't hop on her left. Examination in the eye clinic revealed the fundi to be normal. She was myopic, and glasses were prescribed. An audiogram was done and was normal.

She was seen in Physical Medicine and Rehabilitation because of shortening of her left Achilles tendon. Tendon-stretching exercise and special shoes were prescribed. Laboratory studies including Hgb., WBC, ESR, serology, ferric chloride, UA, skull x-rays and sleeping EEG were normal.

Dr. Branthaver

Dr. Schmitt, would you give the neurologic findings?

Dr. Barton Schmitt*

She had no signs of kernicterus** at that time, such as athetosis, paralysis of upper gaze, deafness or cerebellar problems. The only findings were in the lower extremities with spasticity manifested by abnormal hyperactive reflexes, increase in tone with clonus in the left ankle. The spasticity was definitely more prominent on the left but did not interfere with her ambulation except to give her a clumsy gait. We found no abnormalities in the upper extremities.

Dr. Branthaver

This child has a normal EEG in the face of unequivocal signs of an upper motor neurone lesion. Would you discuss the significance of this?

Dr. Schmitt

The EEG records only the electrical activity of the outer 3 mm. of the cortex, and the lesion causing spastic diplegia may well be subcortical, probably an electrically silent one which would not project to the cortex.

Miss Helen Kretchmer†

The mother was a patient here when Gail was born. She was 17 at the time, came from Wyoming and stayed with an aunt. She was in tenth grade when she became pregnant, having left school in ninth grade after failing math. She had Cs and Ds in early high school years and average in tenth grade.

*Pediatric resident in neurology, University of Minnesota Hospitals.

**See Test Your Word Score Page 779.

†Social worker, University of Minnesota Hospitals.

Gail's stepfather met the mother through her aunt, and this appeared to be an arranged marriage. The couple met in May after Gail's birth and were married in July. He was the youngest of a large family, had asthma, and was "babied." Only two of the family completed high school; Mr. N. completed only ninth grade. He is a very suspicious person and does not associate with persons outside the family. He tolerates Gail when she does not bother him but uses her as an excuse to get angry. He is jealous of his wife and strikes her on occasion, but he has struck Gail only once, as the mother would not tolerate this. The couple has had no children of their own. This is not a happy marriage and Mrs. N. is thinking more strongly of separation and divorce. She has, of late, insisted on Gail's medical care and on being able to associate with neighbors.

The family lives in a two-bedroom trailer park, where there are 200 trailers and 700 people. It is incorporated as a village, and the family has been there for two years.

Mrs. N. said she is convinced that Gail is slow but not retarded. She has observed that the child has periods in which she learns new things, then repeats them for a time. She plays with friends from school and also plays well by herself. She seldom cries but screams after an occasional spanking. When angry, she becomes silent. Our secretary heard her repeat, while waiting alone in the hall, "I'm not retarded, I'm not retarded." Mrs. N. describes Gail as being independent and determined like herself, and there appears to be a very close bond between them. Mrs. N. seems to be growing up and asserting herself more. She went against her husband's wishes to bring Gail here and took a job as a maid in a Howard Johnson motel to earn money for Gail's auxiliary medical expenses. She asked to be told in plain language what Gail's problems are and said she has not had sufficient opportunity to talk with the medical staff here without Gail's presence.

Mrs. Judy Edmonds*

Evaluating Gail's language skills: she is just slightly below her age level in most language skills except those involving the ability to make or understand abstractions through language. She is also slightly below her age level in the ability to recognize forms (seeing a circle for a circle no matter where it is or what it has inside it or around it), and she is quite a bit above her level in the ability to discriminate forms from backgrounds.

Dr. Branthaver

What significance is there in the ability to discriminate forms from backgrounds? Would it indicate more promise to read?

Mrs. Edmonds

I don't attach too much significance to it except that this is an essential skill for learning to read. I think she definitely does very well in that particular area. However, I don't know how well she will understand what

Continued

---

*Speech therapist, University of Minnesota Hospitals.

she reads because of her difficulty in understanding relationships between things.

Mrs. Grace*

I think that the first thing I noticed that made Gail stand out in the class at school was her incessant chatter, an advanced vocabulary, and an inability to do abstract thinking and to relate one situation to another. Some things she could do extremely well, such as working puzzles and stringing beads. Also, she has an unusually good singing voice; she carries a tune very well and remembers it. She can pick out tunes on the piano just by ear. She worked by herself and rather tended to ignore the other children in the group. As time went on, however, she became a little more interested in the other children, but I don't feel she ever really established what would be a good reciprocal relationship with them. The mother has always been quite objective and understanding with the child and very cooperative in giving us any information that might help us in dealing with her.

Dr. Norman E. Silberberg**

Gail was concrete in her perceptionalization, dealing with things and tangibles rather than abstract concepts; she found it difficult to follow directions for abstract tasks. She was in the low educable mentally retarded range. Recognition vocabulary was significantly higher than her expressive vocabulary; that is, she was able to associate pictures with proper words but was not able to express a definition of the word. She perseverated both verbally and in her motor tasks. She had difficulty in integrating parts of wholes and also showed several tendencies to rotate what she saw; for example, she assembled a puzzle upside down; also, when she was asked to write her name, she was able to get the first two letters correct but rotated the G and the A. In some places where it involved assembly of parts into wholes, she was able to name the parts correctly but unable to place them in meaningful proximity to each other. Her auditory perception seemed quite good and she was able to repeat words perfectly even though she was unable to understand their meaning. Possibly, she may learn to read if her visual perception develops to the point where she can then use a more phonetic approach to this skill.

We decided to retain Gail in kindergarten for one more year to give Mrs. N. some added time to seek medical help, and we hope that time may develop in her an understanding of the social amenities in the class in terms of abstract relationships. Following the second year in kindergarten, she is to be placed in a special classroom for the educable mentally retarded, unless there is some medical treatment which might change the current functioning level.

Dr. Harold Ireton†

Recent intelligence and related testing was supplemented by screening for achievement (reading, arithmetic), visual discrimination (matching geometric forms), and visual-motor coordination (copying geometric designs). At face value, intelligence testing indicates functioning in the borderline retarded range (verbal IQ 79, performance IQ 74, full scale IQ 74). However, certain discrepancies within intelligence testing as well as other test results point to the need for more complex definition. Intelligence test results are characterized by scatter among the subtests, including average arithmetic and vocabulary. Gail's Goodenough Drawing is also average for her age. Her reading achievement is appropriate at grade level 1.1.

*Kindergarten teacher, Carver Consolidated School District.

**School psychologist, Carver Consolidated School District.

†Child psychologist, University of Minnesota Hospitals.

On the negative side she demonstrates visual motor coordination somewhat under age five. Over-all, the picture is one of a child who is retarded in some areas of intellectual development but not in others; who has probable difficulties in visual motor coordination, but not in visual discrimination per se; who has difficulties in paying attention and in concentrating and is consequently inefficient in her intellectual operations. While the above configuration suggests possible involvement of the central nervous system, the important point is that while she is retarded in some respects, her educational program should probably be geared to dealing with her problems in attention and concentration and her difficulties with complex coordination. This could probably be best accomplished by having her repeat kindergarten. The label 'retarded' might best be reserved; at present it has only descriptive significance and may be misleading.

Dr. Branthaver

Your one outstanding finding has been the child's difficulty in abstraction. She seems to be well below her age in this regard. Wouldn't this be a rather serious deterrent to achievement and isn't this perhaps a more valid sign of retardation?

Mrs. Edmonds

I think Gail's inability to understand abstractions is, to a large extent, due to the fact that she doesn't understand verbal instructions. They are abstract, and she responds with long, impressive, but quite inappropriate sentences. I think that verbal instructions will have to be supported by example, by dealing with concrete materials, or any other means you can use to help her understand what it is you want her to do.

Dr. Branthaver

Spastic diplegia and impaired intelligence are not unusual sequelae of prematurity. Of all patients with cerebral palsy, 30% are prematures; and of those prematures who have cerebral palsy, 70% have spastic diplegia.[1,2] In one study on spastic paraplegia only 7½% were retarded, which indicates that the two deficits are not necessarily related. Cecil M. Drillien[3] studied 50 prematures in Scotland after they had reached school age. One half were not educable in the regular school; 25% were in the dull range of intellectual functioning and having difficulty in the regular school. The remaining 25% were in the regular school and doing well. A large number (88%) were having behavior problems, though not characteristic of the pattern seen in the minimal cerebral dysfunction syndrome. In another study by Heimer et al.[4] it was found that the incidence of neurologic sequelae correlated significantly with low birth weight and low, unstable body temperature. Lubchenco et al.,[5] in 1963, reported on a group of prematures (birth weight 3 lbs., 4 oz. or less) who were about 10 years of age. Fifty per cent of these children had neurosensory deficits, with 60% having abnormal electroencephalograms. Their school problems were not

Continued

correlated with their IQs since 20 of 35 with normal IQs were having serious academic problems. It is of interest to note that these sequelae did not correlate with the serum bilirubin but did with the low birth weight. This is quite a different prognostic picture than was thought to be true a few years ago.

Dr. Ryan

All this child needs in the way of physical therapy is some stretching exercise to correct the shortened Achilles tendon; the mother has been instructed in this. In addition, corrective shoes have been prescribed.

Dr. Branthaver

The spasticity is not a serious problem, nor does it require extensive therapy. The only problem that might arise would be whether the tendons were so tight as to make her gait difficult. However, the spasticity should not interfere with the over-all planning for Gail's educational program. Whether she should be in the regular or special education classes can be decided only by the school authorities after appropriate observation and evaluation. The mother would like some final decision as to whether Gail is or is not a retarded child. We will attempt to answer this in as direct and honest a way as possible, namely, that she is educable but will have learning problems which will need special management.

Dr. Edward Defoe[†]

I think it should be made clear, however, that the University is not able to offer total on-going medical care.

Miss Kretchmer

In view of the father's antagonism toward physicians, I would expect that Gail would not be under a physician's care in her community. What continuing supervision might be available?

Dr. Branthaver

I don't visualize any significant change taking place in the father's attitudes, since he has not involved himself in Gail's problem. We are left with the school taking responsibility for the educational program and the University continuing to be responsible for her minor motor dysfunction. On the positive side, we have a responsible mother who probably will seek help as significant problems arise and will be receptive to suggestions given by the school.

In summary, we have a child who has neurosensory deficits as sequelae of a premature birth. Her learning handicaps are such that special instruction may well be essential, and some methods of approach have been discussed. The decision relative to the management of her educational program must rest completely with the school. Her spastic diplegia is mild and should not prove to be a significant handicap. There is need of continuing medical supervision, and this can be provided through the Physical Medicine and Rehabilitation Department here at the University Hospital. If necessary medical supervision can be offered, though less adequately, through the general pediatric outpatient clinic.

I would like to express my appreciation for the participation by Mr.

[†] Pediatrician, University of Minnesota Hospitals.

Karnuth, Mrs. Grace and Dr. Silberberg from the school district. Without their contributions this evaluation would not have been possible.

Charles Branthaver, M.D.

Mildew on the Little Black Bag

Tradition has associated the physician with the little black bag: the universal and esteemed signal that here comes, or there goes, the doctor. The bag may be new; it may be old or even dilapidated; whatever its condition it is the visiting physician's exclusive hallmark. His distinctive charisma derives, not from his clothes, his manner, his conveyance, but from the little black bag he carries.

The doctor and the little black bag are a team. A house call without the bag is a disappointment, if not an affront, to the patient, the family, and even the neighbors. It is almost a breach of promise!

The official opening of the bag at the bedside is invested with a ceremonial aura of expectancy that gives courage to the patient and hope to the family. No one, neither the patient nor the bystanders, not even the doctor himself, knows exactly what the bag contains. From its mysterious depths can be extracted one by one an incredible assortment of instruments for examinations, needles for injections, drugs for sedation or therapy, not to mention other incidentals with wholly arcane functions.

Every physician has a personal and symbiotic attachment to his bag. Dr. Bagley (no pun intended) recently said: "You cannot carry a little black bag for years without making a lasting friendship with it. Further, the bag readily makes friends with the patients." Telephone advice, office, clinic, or hospital care can never assure the physician of the family's confidence that follows a house call with the little black bag. There is no substitute for it; from it emerges for the physician an invaluable graduate training, inaccessible to the doctor without the experience of house calls in company with the little black bag.

Hippocrates may or may not have had a little black bag to carry about with him; but the oath states: "Into whatever *houses* I enter, I will go to the aid of the sick." There is no place like the patient's home and bedside to learn the art of medicine — with the little black bag at his and your service.

Therefore, preserve that charismatic little bag, carry it, and use it. And some quiet evening place it reverently beside you as you doze in the rocking-chair and reflect on the sorrow and joy, the failure and success, the sacrifice and devotion you and the little black bag have so profitably and intimately shared together.

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown®
(meprobamate)

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its antianxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of preexisting symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

Medical Seminar

Biologic Defiance to Transplantation

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

THE PROSPECT OF treating patients by replacing diseased organs with allogeneic transplants of normal organs (homografts in the old terminology) has become a major concern of experimental medicine in recent years. The vast literature on the subject includes reports showing that virtually every organ and tissue have been used as allograft material in a wide variety of experimental settings. Except for a few special situations, such attempts have fallen short of complete success because within a few days or weeks the grafted material is destroyed by the recipient. This phenomenon is termed "rejection" and constitutes the prime obstacle to successful allogeneic transplantation. A consideration of the rejection reaction is the subject of this presentation.

A simple observation demonstrates that the rejection reaction to allografted tissue is an immune reaction. In the first encounter of an unmodified recipient mouse with an allograft of skin, destruction of the graft occurs and rejection is complete in about 10 days. This is termed the "first-set reaction." However, when the recipient is challenged a second time by an allograft from the same donor, rejection is greatly accelerated and may be complete in five days or less. This is termed the "second-set reaction" and constitutes a typical immunologic, anamnestic* response. Contact of the antigen, namely the allograft, with the immunologically competent recipient must take place before the reaction can occur and graft necrosis is the result.

The rejection reaction arises in an artificial setting and has no natural counterpart. Therefore, it seems more appropriate to use the term "biologic" rather than "physiologic" with respect to the host's defiance to transplantation. The "physiologic" significance of this mechanism, if there is one, is unknown.

Genetic Considerations

The description of the rejection reaction includes some pertinent genetic considerations. The rejection reaction will not take place when a transplant is made between identical twins. Similarly, a genetically uniform population of experimental animals, for example, an isologous strain of mice produced by inbreeding (repeated brother and sister matings over many generations) will freely accept grafts from one another without incident. However, a graft from a male to a female of the same inbred strain, by definition, introduces a genetic dissimilarity since the female does not possess the "y" chromosome of the male. This graft may therefore be rejected in some strains.

Hybrid Offspring

When a member of one strain is crossed with a member of a different strain, the resultant F_1 hybrid offspring will possess the genetic characteristics of both strains. The offspring will accept a graft from either parent without a rejection reaction occurring. By contrast, a member of either inbred parental strain will not accept a graft from the F_1 generation hybrid because the hybrid possesses antigens not shared by either parent alone. Subsequent crossbreeding with

Continued

---

*See Test Your Word Score Page 779.

still other strains introduces additional genetic dissimilarity and results in a stronger rejection reaction when a graft is attempted to a member of any of the parental strains.

Mongrel Offspring

A mongrel population, such as the human population, introduces the possibility of a relatively large number of genetic dissimilarities between individuals. It may be anticipated that a graft from an individual in this population will be rejected by most others of that population. Therefore, genetic factors are of fundamental importance in determining the occurrence of the rejection reaction in the host.

Why does genetic dissimilarity permit allograft rejection? In order for an antigen to perform as such, the host's reticuloendothelial system must recognize that antigen as foreign to itself. In the antigenic donor cells, it is not the genetic material per se (the DNA) which is recognized as antigenic by the host. Rather, the genetic material merely performs its usual duty of directing the production of the various molecules concerned with normal cell structure and economy. These resultant molecules will differ slightly from one individual to another, reflecting genetic dissimilarities. Furthermore, it is these molecules, the normal components of the graft cells, which are antigenic and treated as such by the graft recipient. These molecules, when considered in the context of transplantation, are termed "transplantation antigens." Similarly, the specific genes responsible for their production are termed "histocompatibility genes." Since the classical concept of the "gene" is no longer adequately defined, perhaps it would be preferable to term the latter "histocompatibility loci" on DNA molecules.

Inbreeding

Sophisticated experiments involving inbred mice of known genetic composition have given evidence of a number of histocompatibility loci. By selective breeding techniques, these loci can be tested individually or in combination in terms of their ability to induce a rejection reaction. A graft that differs from its host in only a few loci will be rejected much more slowly and with a less violent reaction than one with a high degree of genetic dissimilarity. Such experiments also have demonstrated that individual histocompatibility loci differ in the strength with which they will induce a rejection reaction in a recipient that lacks this locus.

The single histocompatibility locus in the mouse that is capable of inducing the strongest rejection reaction is termed the H-2 locus. (The H-2 locus is one of several so-called "H" loci. Their corresponding antigens are termed "H" antigens. These are termed "H" loci and "H" antigens because early work demonstrated their conspicuous ability to induce formation of "hemagglutinating" antibody. Their function as transplantation antigens, however, has subsequently been clearly established.) This H-2 locus is probably composed of 20 alleles and is responsible for the existence of several transplantation antigens in the cell.

Immunofluorescent and fractionation techniques have demonstrated that these H-2 derived antigens probably are located in the cell membrane and intracellular membranous structures and, chemically, are believed to be lipoproteins. It is interesting that the H-2 derived antigens seem to undergo maturation. They are relatively weak immediately after birth, but rapidly increase in potency and achieve about 50% of their adult potency by nine days of age.

Such detailed genetic information results from studies carried out in mice, but similar data are not available for other species, including man.

Immunologic Considerations

What happens when an allograft is applied? Basically, three things take place. There is (1) a local host cellular response, (2) rejection and destruction of the graft, and (3) the appearance of circulating antibody. It was pointed out that direct contact of antigen with the reticuloendothelial system of the host is obligatory in order for a rejection reaction to develop. The antigen gains access to the host at the graft-host interface. In organs such as the kidney, this interface is established immediately by uniting the graft and host blood vessels in the technique of grafting. The interface, then, consists of the vascular endothelium of the graft and the bloodstream of the host.

The graft-host interface is somewhat different in skin grafts. Vascular channels develop only as healing proceeds. But these channels are not essential for sensitization to occur, since repeated removal and replacement of the graft, preventing establishment of vascular channels, does not prevent sensitization. Therefore, the graft bed itself is the interface, and cell debris is the antigen. The graft bed later becomes the site of intense infiltration by host cells, confirming the local reaction to the graft.

Having entered the host circulation, antigen exerts a systemic effect on the host lymphoid tissue. In skin grafts, the regional lymph nodes draining the graft site are the first to show this effect, but soon distant lymphoid tissue is affected.

Morphologic evidence of this encounter between lymphoid tissue and antigen becomes evident at about three days after grafting. Large pyroninophilic cells appear and proliferate, causing enlargement of germinal centers. Under the electron microscope, small clusters of ribosomes and little endoplasmic reticula are evident in the cytoplasm of these cells. As time passes, plasma cells, with extensive endoplasmic reticula and many ribosomes, appear in increasing numbers. Maximal activation occurs on about the ninth day.

The development of this reaction in host lymphoid tissue is associated with the appearance of a cellular reaction at the graft site and the appearance of gamma globulin antibodies of several types, including hemolysins, hemagglutinins, and cytotoxins. Considerable controversy has raged regarding the relative importance of the cellular response versus the humoral response in the development of the rejection reaction.

Some investigators have stated the belief that cells are essential to the rejection reaction. These "cellular theorists," championed by Medawar, stress the importance of cell-bound antibody and the local cellular reaction. One of their main arguments concerns the observation that transplantation immunity cannot be passively transferred to an indifferent animal by antibody-containing serum but can be transferred by sensitized lymphocytes.

Other investigators assert the role of circulating antibody in the rejection reaction. These "humoral theorists," led by Stetson, have demonstrated that immunity to a transplant can indeed be passively transferred by serum if the graft consists of single cells rather than an aggregate of a large number of cells in a tissue or organ.

Both the "cellular" and "humoral" theories of allograft rejection are supported by much additional data. The importance of cells is suggested by the fact that the layer of sensitized host mononuclear cells surrounds a skin graft undergoing rejection. If, however, the graft is enclosed in a millipore chamber such that the host cells are prevented from directly contacting the graft, the graft is preserved.

The importance of humoral factors is by no means excluded by these data. There is valid evidence that the millipore chamber not only excludes host cells but also prevents circulating antibody and complement from reaching the graft in significant concentrations. Furthermore, accelerated graft rejection may indeed be accomplished with passive transfer of circulating antibody to an indifferent animal. This can only be achieved, however, if the antibody is harvested at the height of the initial rejection reaction. This capacity is not present in immune serum harvested at a later time, or after repeated stimulation with graft antigen, even though antibody titers become much higher. This indicates that "early-appearing" antibody differs from "late-appearing" antibody. Earlier work demonstrating the ineffectiveness of passively transferred humoral antibody employed only the ineffective "late-appearing" antibody.

It is interesting that "early" and "late" antibodies can be distinguished chemically. Initial antigenic stimulation elicits an anti-

Continued

body response of the 19S (immunoglobulin M) variety. In contrast, the antibodies elicited in the anamnestic response are of the 7S (immunoglobulin G) type. Although this difference has been observed, the relation between antibody type and the ability to induce passive graft sensitization is unknown.

Regarding the nature of cell-bound immunity, it has been pointed out that transfer of sensitized lymphocytes to an indifferent animal will impart sensitization to that animal. If these cells are tagged with a radioisotope, they distribute themselves throughout the lymphoid system of the host. When the animal is subsequently challenged by an allograft, the host's cells (but not the injected tagged cells) appear at the graft site where rejection takes place. A similar passive sensitization can be achieved even if the transferred sensitized lymphocytes are enclosed in a millipore chamber, preventing direct contact with the unsensitized host. Sensitized cells thus are capable of imparting sensitization to other immunologically competent cells, and the existence of a subcellular factor capable of leaving the millipore chamber to effect this is suggested.

Subsequent work has led to the demonstration of just such a "transfer factor" with this property in extracts of human and rodent lymphocytes. This factor is effective in imparting enduring sensitization in minute quantities. Injection of as little as 0.1 ml. of a cell-free lymphocyte extract will be effective. The exact identity of this factor is unknown, but it seems to withstand freezing, distilled water lysis, and treatment with desoxyribonuclease, ribonuclease, or trypsin. Despite the apparent ribonuclease resistance, other investigators have achieved the "transfer effect" by direct use of RNA extracted from sensitized cells. Further work is needed to reconcile these views.

Thus it has been shown that the act of transplantation results in observable changes in the immunologically competent lymphoid tissue of the host. Theories regarding the mechanism by which activated lymphoid tissue effects graft rejection have stressed the importance of cellular and humoral factors. To date, the relative significance of these mechanisms in allograft rejection is unknown.

The Host-Versus-Graft Reaction

Certain events take place within the graft itself. Although full antibody response does not develop for several days after transplantation, there is an immediate interaction of graft and host that touches off the chain of events leading to rejection. Although the precise role of cell-bound and circulating antibody is ill defined, such antibody can be regarded logically as being essential to the rejection reaction. It is generally conceded that graft-cell destruction may be accomplished by combinations of antibody with antigen in the presence of complement. The obvious site for damage to appear first is the graft-host interface. Since the blood supply to the kidney is established in the technique of transplantation, the kidney allograft differs considerably from, for example, a skin graft, and a detailed look at the sequence of events taking place in the allografted kidney is worth considering.

In experimental animals, small lymphocytes make contact with capillary endothelium almost immediately after the kidney is transplanted. Two or three days later, cells that appear to be large lymphocytes or histiocytes are seen clinging to the peritubular capillary endothelium. The intervening cell membranes between endothelial and mononuclear cells quickly disappear, and cytoplasmic continuity is established. Resultant endothelial damage encourages deposition of fibrin, platelets, and cell debris. Progressive narrowing of the graft vessels ensues, blood perfusion diminishes, and ultimately signs of infarction and necrosis become apparent. Interruption of the blood supply has efficiently ended the life of the organ.

The predominating vascular reaction is accompanied by a progressive increase in plasma cells and deposition of gamma globulin on the media of the interlobular arteries. Terminally, there is increasing edema and infiltration with neutrophils and macrophages. All function ceases between the fifth to the eighth day.

That the blood supply to the kidney is established in the technique of grafting distinguishes the kidney transplant from the skin transplant. It has been shown earlier that vascularization of the skin graft is not necessary for sensitization to occur. Similarly, vascularization is not necessary for skin graft rejection. This is exemplified by the so-called "white graft" reaction. This occurs when a second skin graft is applied to an individual previously highly sensitized and is demonstrated especially easily in rabbits. The reaction is so violent and rejection so rapid that there is no chance for vascularization of the ischemic graft to take place.

Summary and Conclusion

The rejection reaction is basically an immune one. It is permitted to develop, fundamentally because genetic dissimilarities exist between graft and host. Genetic dissimilarities are reflected in dissimilar molecular cell constituents which the host recognizes as antigenic. Histologic evidence that the host has encountered graft antigen appears within host lymphoid tissue. Shortly thereafter, humoral antibody appears and a local cellular reaction develops at the graft site. The graft is subsequently destroyed. Current data do not permit a definitive statement as to the relative importance of circulating and cell-bound antibody in the rejection reaction.

Transplantation, as such, is a man-made artefact. With the possible exception of pregnancy, it has no known natural counterpart. The physiologic justification for the existence of the observed reaction to a graft is not understood. Could it be that this is a normal homeostatic mechanism suppressing the proliferation of cells undergoing neoplastic transformation? Why, then, are the genetic alterations in neoplastic cells not recognized as such and destroyed in all cases? Although specific antigen and anti-tumor antibody have indeed been demonstrated, could there be a breakdown at some point in a "natural" rejection reaction?

In the final analysis, the greatest ultimate benefit from transplantation research may not be the successful transplantation of organs at all, but rather a deeper understanding of the function of the immune system and its clinical significance.

Pharmacopoeia of the Colonial Physician

His pharmacopoeia consisted mainly of simples, . . . St. John's wort and Clown's All-heal, with Spurge and Fennel, Saffron and Parsley, Elder and Snakeroot, with opium in some form, and roasted rhubarb and the Four Great Cold Seeds, and the two Resins . . . with the more familiar Scammony and Jalap and Black Hellebore. . . . He would order Iron now and then and possibly an occasional dose of Antimony. He would perhaps have had a rheumatic patient wrapped in the skin of a wolf or wild cat, and in case of a malignant fever with 'purples' . . . or for an obstinate king's evil he might have prescribed a certain black powder, which had been made by calcining toads in an earthen pot. . . . Sydenham had not yet cleansed the Pharmacopoeia of its perilous stuff, but there is no doubt that the more sensible doctors of that day knew well enough that a good honest herb-tea which amused the patient and his nurse was all that was required to carry him through all common disorders. — Oliver Wendell Holmes

Diarrhea and Anuria

Dr. Robert Good*

This 20-month-old white female was admitted to University of Minnesota Hospitals on April 15, 1963, because of persistent vomiting, a gastrointestional disturbance, and strange behavior which might be attributable to disease of the central nervous system. She experienced an upper respiratory infection which began April 5, 1963, and was treated with aspirin.

Anorexia occurred on April 11, 1963, followed by one large emesis the next evening. On April 13 vomiting followed each meal, and the vomitus was said to contain black flecks. Following this the child began to pass green and brown-black liquid stools. Her parents noted that she slept most of the day and, when awake, would stare in a strange fashion.

On the following day, April 14, she vomited constantly, had four to five liquid green-brown stools, and received one teaspoon of a paregoric-kaopectate preparation every two to three hours. She retained some of this medication plus some carbonated beverage. Because of the diarrhea, it was not known whether she had urinated during the day prior to admission.

According to the history she had been slow in her development. She didn't sit until she was ten months of age; she didn't walk until she was twenty months. She required a gastric lavage three weeks prior to admission because of Enovid ingestion. The family used well water and was having difficulty with a partially obstructed cesspool.

Physical Findings

She was a pale, acutely ill, motionless, staring child reclining with flexed knees and exhibiting an occasional loose cough. Vital signs were BP 90/60, R 22, P 140, and T 98. The temperature is significant. Findings included a flat, scaphoid abdomen and guarding in both lower quadrants. She had some abdominal tenderness, moderately hypoactive bowel sounds, and questionable bilateral costovertebral angle tenderness.

Laboratory Findings

The admission hemoglobin was 11.6 and the white blood count 64,250. She had 80% polymorphonuclear leukocytes, 18% lymphocytes, and 2% mononuclear cells. Prior to the intravenous therapy the serum electrolytes were within the normal range. No acidosis was present. Her sodium concentration was normal, but her BUN was elevated to 57 mg.%. Initial fluids consisted of 100 cc. of plasma every two hours followed by a ⅓ N saline flush of 150 cc. in 45 minutes. Because of failure to void, ⅓ N saline was continued at 1200 cc/M^2/day.

At 8 a.m. on the morning of admission a peritoneal tap and a spinal tap were performed. The peritoneal fluid showed red blood cells and white blood cells and a significant amount of protein, 1.6 gram%. The lumbar tap showed a normal opening pressure of 130 mm. The protein and sugar were normal. There were red blood cells, however, in the tap. No indication is given as to whether or not trauma was associated with the tap.

Continued

---

*Professor, Department of Pediatrics, University of Minnesota.

Progress

At 10 a.m. the blood pressure was recorded and found to be elevated at 140/90. Intermittent tonic movements of the limbs were noted, and the child had seizures followed by two grand-mal seizures without evidence of focal origin. Blood was drawn and showed a sodium of 127 mEq/L. and a potassium of 4.2 mEq/L. The chloride was 87 mEq/L. and the CO_2 18 mEq/L. The BUN had gone up to 62 mg.%, sugar was 187 mg.%, calcium 8.2 mg.%, and the magnesium 2.1 mEq/L. — a normal value. But the physicians were unaware of the electrolyte data, and a 125 cc. of ⅓ N saline was given for over a one-hour period without resultant voiding. Because of apparent renal shutdown, the fluid therapy was altered to 10% glucose, and distilled water was started at a rate of 500 cc/M^2/day. Fluid intake that day, including plasma, totaled 900 cc.

Another grand-mal seizure occurred. It began with a right-sided tonic movement, became generalized, and was associated with cyanosis and respiratory arrest. The child was successfully resuscitated and given 10 cc. of 3% sodium chloride and 0.75 cc. of intravenous paraldehyde. A repeat white count was 104,000. Any count over 100,000 is supposed to signify leukemia, but I would except this case. I will return to the extremely high white count later.

I consider the ingestion of Enovid establishes the existence of pica.* I am not able, in working out this puzzle, to implicate Enovid as being of any pathogenic significance. Her ingestion of Enovid indicates that this little 20-month-old child was capable of ingesting strange items. A 3-year-old male sibling had a concurrent upper respiratory tract infection without gastrointestinal symptoms. However, the cesspool problem probably is a red herring rather than the red flag, but the well and the plumbing might provide exposure to gram-negative bacterial infection from feces. I think that both the abdominal and costovertebral angle tenderness represent pertinent data. The passage of 3+ guaiac positive stools and of red liquid feces is also important and perhaps critical information.

The serum osmolarity on April 15 was 300 mOsm/L. This is at the upper limits of normal and reflects, I think, either an elevation of the blood urea nitrogen or the retention of other products from renal shutdown.

The blood pressure throughout the first hospital day was elevated. A fairly stable evening was interrupted by occasional spasms and "frog-leg" movements of the extremities, a presumed seizure pattern which was treated with intravenous paraldehyde. On the morning of April 16 Cheyne-Stokes respirations were observed and followed at 11 a.m. by cardiopulmonary arrest. Resuscitation measures were unsuccessful.

At no time during the admission did the child void. During the approximate 36 hours of hospital care, her temperature varied from 98° to 102°. Her weight was 8.85 kg. on admission and 8.9 kg. on April 16.

During the period of hospitalization the child was given one million units of aqueous penicillin and chlortetracycline 10 mg. intravenously every hour. She had nine doses of this preparation.

I wonder if we might see the x-rays, because I have some questions I would like to ask about them.

Dr. Leonard Langer**

The chest x-ray shows some patchy infiltrate at the right medial base. On the lateral film there appears to be some fluid in the major fissure adjacent to the infiltrate. An abdominal film taken early on April 15 shows some dilatation of small bowel loops. No colonic gas is visualized. This suggests a mild ileus of the paralytic type rather than a mechanical obstructive proc-

---

*See Test Your Word Score Page 779.

**Assistant Professor, Department of Radiology, University of Minnesota.

ess. There is no evidence of ureteral reflux on the cystogram. However, on this film we do see an abnormal segment of colon. There are gross erosions of the colonic wall without any thickening of the wall of the dilated small bowel loop. The erosions seem to be limited to an area of transverse colon.

Dr. Good:

Although the protocol indicated that ulcerative colitis had been a consideration, we see no evidence of chronic disease of the colon. A more acute ulceration of the bowel seems a more likely possibility.

Our problem then is a 20-month-old child who had a respiratory infection and developed central nervous system symptoms which included confusion, disorientation and, several days later, seizures. The central nervous system manifestations were noted prior to fluid therapy. The child also had a history of pica. Then she developed bloody diarrhea and vomiting. The profuse vomiting was associated with hypertension, urinary shutdown, anuria, azotemia, and intestinal ulceration. In addition, the white blood cell count was 104,000.

Now, Dr. Langer, could you visualize the kidneys in any of your films, and could you estimate their size?

Dr. Langer

We see the kidney outlines reasonably well on the films. They don't appear grossly abnormal.

Dr. Good

I just wanted to be sure that the kidneys weren't extremely small or unusually large.

Poisoning

Certainly in a child with pica, we consider an intoxication as a basis for the damage to the central nervous system, to the kidney, and to the bowel. This combination of manifestations could be secondary to arsenic ingestion. In April in Minnesota it is possible to find rat poisons containing arsenic. Mercury is another possibility. No evidence was obtained of exposure to either of these compounds. This reassures me but does not lull me into complacency.

A few years ago we had a youngster who had apparently ingested a bismuth compound used in the treatment of warts. This child had a severe renal shutdown but no central nervous system or gastrointestinal disease. However, when I first began my pediatric studies at the Minneapolis General Hospital, two little children came in with central nervous system manifestations, drooping eyelids and severe gastrointestinal manifestations; and they rapidly developed anuria. Those children had ingested some rat poison that they had taken from the incinerator box in their apartment house. We finally made the correct diagnosis when their hair began to fall out. They were suffering from *thallium* intoxication.* This possibility must be kept in mind. Also, in April in Minnesota when car radiators are changed, a child, particularly an active child, who tends to

---

*See Test Your Word Score Page 779.

Continued

put things in his mouth, might ingest sweet-smelling but non-nutritional substances such as anti-freeze, which can destroy the brain and kidneys. Ethylene glycol can produce a rapidly developing renal failure, as well as gastrointestinal and central nervous system manifestations. Poisoning, of course, is one of the common causes of morbidity and mortality in children and may appear as a bolt out of the blue in a child who has been vigorous and healthy.

Shigellosis

Also, with this combination of manifestations, one has to think very strongly of an infection from Shigella. This organism produces a potent neurotoxin and can, as a consequence, cause a very severe gastrointestinal upset with central nervous system symptoms. Renal damage is unusual but can occur with Shigella, especially with severe dehydration. Renal vein thrombosis occurs especially in young children who are dehydrated. Further, in a few case instances, bilateral cortical necrosis of the kidneys has been observed in patients with shigellosis. In this case the history about the defective water supply may be a clue. However, most shigellosis infections are transmitted by person-to-person contact.

The gastrointestinal manifestations of shigellosis occur after a short incubation period. It would be unusual to have central nervous system manifestations preceding gastrointestinal manifestations by the length of time intervening in this instance. The patients are usually febrile and show much toxicity. The toxicity was present here, but the temperature was normal. The stools were not like those usually observed in shigellosis, but again there is much variability, especially in small children. The diagnosis must be made, of course, by stool culture. The early onset of the central nervous system manifestations preceding the gastrointestinal symptoms, the lack of febrile course, and the atypical character of the stools make the diagnosis of shigellosis unlikely.

Acute Pyelonephritis

Acute pyelonephritis may present with primary gastrointestinal manifestations. With the acute toxicity there also may be convulsions and central nervous system disturbances. In a few of these patients the disease may be so fulminating as to produce the picture of renal shutdown. However, all of these things are associated with high fever, and she would have to have all the unusual manifestations of pyelonephritis in order to explain this case on that basis.

Chronic Renal Disease

In very young children, acute renal failure may follow respiratory tract infection or a gastrointestinal tract infection. Such a history may be observed, for example, with polycystic kidneys or in hypoplastic or dwarfed kidneys. These patients may limp along in borderline compensation, only to develop acute renal failure in the face of an acute infection.

Chronic nephritis with chronic nephropathy associated with obstructive uropathy can terminate with surprising suddenness after acute infection. The size of the kidneys makes dwarfed or polycystic kidneys an unlikely choice.

Cortical Necrosis

Bilateral cortical necrosis syndrome should be foremost in our minds. First of all, we have to explain this extremely high white count. Among the few conditions besides leukemia that can present in childhood with a high white count in the 50-100,000 range is bilateral cortical necrosis of the kidney. Bilateral cortical necrosis also may definitely occur as a consequence of gastrointestinal infections or be associated with gastrointestinal infections and also with convulsive disorders, as was pointed out by Zuelzer[1] et al. long ago. The gastrointestinal manifestations and the kidney disease could occur together here, with the primary disease probably being the gastrointestinal infection and the bilateral cortical necrosis secondary. Ulceration of the bowel may also be observed in this association.

Hemolytic Anemia-Uremia Syndrome

In 1955 Gasser[2] described a syndrome, of which there are now at least 50 case reports. I am speaking of the hemolytic anemia-uremia syndrome. One observes severe central nervous system disease, usually with convulsions, often with cyanosis, progressive anemia, (although the hemoglobin at the initial presentation in a few of the cases has been very close to the normal range), thrombocytopenia and rapidly developing renal insufficiency. The patients regularly present with vomiting or diarrhea which generally has been present from two to ten days and rapidly develop pallor, dehydration, convulsions, and hypertension. A few of them have petechiae. About 35% die with this syndrome, and bilateral cortical necrosis of the kidney has been present in some. The kidney in others shows a severe fulminating glomerulonephritis. The pathological picture may be like that seen in severe acute glomerulonephritis or subacute glomerulonephritis.

Hemolytic anemia is very interesting because it is usually a Coomb's negative hemolytic anemia. Few patients present jaundice. The peripheral smear shows red blood cells with fragmentation, poikilocytosis* and acanthrocytosis.* Especially significant in light of our patient today was the case reported by Shumway and Miller[3]. In this case the hemolytic anemia and the renal disease were *dissociated* in one episode and *associated* in another episode in the same patient. That is to say, the patient presented one episode where an intimate association of the hemolytic anemia and the uremia was observed; and another in which the glomerulonephritis was present without the hemolytic anemia, and then later the hemolytic anemia again developed.

Moschocowitz Syndrome

A final possibility is primary thrombotic thrombocytopenic purpura or Moschocowitz's syndrome. I am not sure how well the bilateral cortical necrosis of the kidneys and the hemolytic anemia-uremia syndrome of Gasser can be separated from thrombotic thrombocytopenic purpura. At least, pathologically, most of the cases do not show an overlap.

In thrombotic thrombocytopenic purpura, the primary material being deposited peripherally in the small arterioles consists of clumps of platelets entrapped in fibrinoid material or even fibrin. The lesions may involve the small arterioles or the arteriolar side of the capillary circulation. Certainly this disease is rare in young children. It has, however, been described, and we have observed a couple of cases. In a few instances classical thrombotic

---

*See Test Your Word Score Page 779.

Continued

thrombocytopenic purpura may be the initial manifestation of lupus erythematosus. This pathologic process certainly can produce a combination of severe gastrointestinal disease, severe, rapidly progressive renal disease, and severe nervous system disease, all of which were present in our patient.

The syndrome of Gasser, the hemolytic anemia-uremia, is the most common of the severe, rapidly destructive diseases in children. All this patient's manifestations would be compatible with this possibility. The admission hemoglobin of 11.6 is the red flag against this diagnosis and favors bilateral cortical necrosis of the kidney with gram-negative bacterial sepsis. I favor this latter diagnostic possibility. On either basis what we will likely see at autopsy is bilateral cortical necrosis of the kidney as a reflection of the more generalized vascular disease. In the hemolytic anemia-uremia syndrome, which usually occurs in children of under one year or in older children, the glomeruli of the kidney are loaded with gamma globulin deposits.

Gamma Globulin Deposits

How do these gamma globulin deposits occur? I think the best bet, although nobody knows the mechanisms of the hemolytic anemia-uremia syndrome, is antigen-antibody complexes form from exogenous antigen and an antibody being produced in the body. The hemolytic anemia and renal disease are not necessarily dependent upon one another. Peter Miescher has shown clearly that antigen-antibody complexes have a selective affinity for red blood cells, which can act as innocent bystanders in receiving toxic soluble antigen antibody complexes from the circulation. These attach to red cells by a process known as immune adsorption, render the red cells abnormal and lead to their rapid destruction.

Shulman has demonstrated the same pathogenetic basis of thrombocytopenia in some cases of drug-induced thrombopenia. Dixon and his coworkers have shown clearly that the kidney also may function as an innocent bystander in immunological disease and can be the subject of assault by these same toxic, soluble antigen-antibody complexes. In light of the Shumway-Miller case, the best consideration of the pathogenetic mechanisms in this disease is that you have both of these systems: red blood cells and kidneys receptive of damage from such a source, sometimes together — sometimes separately.

Soluble Antigen-Antibody Complexes

Shulman also has recently shown that platelets may be damaged, not by a direct attack of the immunological mechanism on the platelets, as in auto-immunity, but by an attack of the soluble antigen-antibody complexes attacking the platelets again as innocent bystanders and producing damage to these cells. So I think we will find gastrointestinal inflammatory disease with ulceration on the postmortem. Although this may be an underlying chronic process, I think it is acute. At least the x-rays suggest this was the case. I would expect there would be evidence of vasculitis in the bowel and perhaps acute necrotizing vasculitis. I recently saw a case in St. Louis with exactly the same syndrome, in which the bowel was involved in a clearly destructive vasculitis which had apparently preceded by some considerable period the development of the renal disease and bilateral cortical necrosis of the kidneys.

Multiple Kidney Lesions

In the kidneys we could have any of several lesions. We could have a true bilateral cortical necrosis, bilateral renal necrosis without limitation to the cortex, or we could have severe acute glomerulonephritis or subacute glomerulonephritis with marked endothelial proliferation. Because of the very high white count, I expect to find bilateral cortical necrosis of the kidneys with deposits of hyalin fibrinoid material in the kidney, just as we see in the generalized Shwartzman reaction in the rabbits Dr. Thomas and I studied so intensively here a few years ago.

Central Nervous System

So far as I am aware, the central nervous system has not been well studied in the hemolytic anemia-uremia syndrome. If this is related to the other pathogenetic mechanisms, I would presume that the central nervous system manifestations would be the result of a destructive occlusive vasculitis — a consequence of intravascular coagulation. I do not attribute the central nervous system manifestations in this child entirely to the water intoxication which I think she had to some degree. The latter may have been contributory to the expression of central nervous system abnormalities but was not primary. Rather, I think this child was loaded with water at the time and could not deal with the fluid, and this may have contributed to the convulsions; but I think the central nervous system disease, as seems clear from our history, antedates the production of a low sodium state. This, then, is my analysis of this patient!

Dr. Good's Diagnosis: Bilateral Cortical Necrosis of the Kidneys

Dr. William Krivit*

Hemolysis can cause an elevated white cell count. But the amount of hemolysis was slight, as the hemoglobin was stable and there was no evident jaundice. Bleeding can also cause leucocytosis. But I wonder whether or not the white blood count of 104,000 might more properly relate to an infectious process such as shigellosis.

Dr. Good

The only infections that I am familiar with that alone will produce a white count of this sort are severe generalized septicemias with extensive peritoneal involvement or pertussis. Pertussis is always associated with a lymphocytosis but is not common. In bilateral cortical necrosis of the kidney, even without a hemolytic anemia, very marked elevation in the white count occurs. We frequently produce bilateral cortical necrosis of the kidney in our rabbits over in the laboratories through the agency of generalized Shwartzman's reaction. The white count of hemolytic anemia-uremia syndrome is sometimes in the 40,000 to 60,000 range. I found none yet reported as high as 104,000.

Dr. Joseph St. Geme**

Attempts to isolate Salmonella or Shigella from several fecal specimens and from a piece of bowel obtained at postmortem were unsuccessful. Multiple cultures of the blood were also negative, as well as cultures of

---

**Assistant Professor, Department of Pediatrics, University of Minnesota. Presently Associate Professor, Department of Pediatrics, U.C.L.A., Los Angeles, California.

Continued

the spinal fluid, pericardial fluid and peritoneal fluid. The only microbiologic recovery, and I don't think it is significant, was an adeno-virus type I, which is usually a nonpathogen, frequently prevalent in the community, and which was also present in the feces of another child on the ward at the same time. This virus was recovered from a piece of bowel.

Dr. Robert Ulstrom*

The probabilities of this being an acute poisoning in this child are so great that it would be urgent to determine what the poison was. Some heavy metal poisons do have specific antidotes which can be administered even relatively late after the acute poisoning.

Dr. Good

I would certainly agree on the combination of manifestations in a child with pica. However, intoxication doesn't usually give this high a white count, and I placed it low on the list. We should always, in a patient like this, be exhaustive in our search for a toxic agent. We may uncover something that can be manipulated to the benefit of our patient.

Postmortem Findings

Dr. Stanley Stark**

Toxicology specimens were taken, but they were not sent to the proper laboratory. There was 20 cc. of clear yellow fluid in each pleural cavity and 10 cc. of serosanguineous fluid within the peritoneal cavity. Frank peritonitis was absent on gross inspection. The heart and lungs appeared grossly normal. Their weights were normal. The most striking finding was seen in the large bowel. Starting about five centimeters proximal to the iliocecal

---

*Presently, Professor, Department of Pediatrics, U.C.L.A., Los Angeles, California.

**Resident, Department of Pediatrics, University of Minnesota.

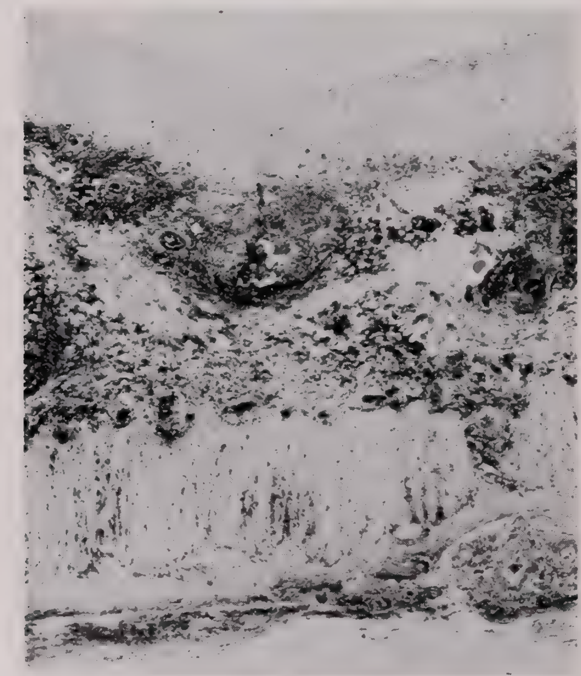

Fig. 1 — This shows extensive necrosis of most of the wall of the colon. There is some sparing of the smooth muscle in the outer portions of the colon wall. x35

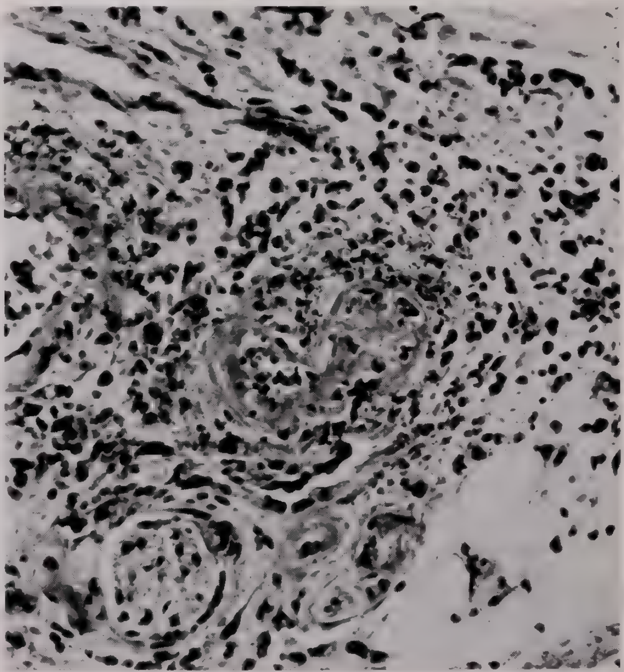

Fig. 2 — This shows necrosis and inflammation in the small vessels in the wall of the colon. x450

valve and extending to the rectum, the bowel had a very striking red-brown color. Even the appendix was involved. When the bowel was opened, there was brown-red debris on the mucosal surface.

The kidneys were of normal weight for the child's age, but grossly had a very swollen appearance. They were deep brown-red in color and, when cut, the kidney tissue actually bulged forth. The color of the cortex was brown-red with several pale foci 1-2 mm. in diameter. The large vessels of the bowel and kidney were traced and were patent and normal.

Dr. Barbara Burke*

The most interesting microscopic findings were those of the colon and the kidneys. There was extensive necrosis of most of the wall of the colon in the areas sectioned. The degree of necrosis and the extent of inflammatory reaction were marked in the mucosa. There was minimal serosal involvement. Viable smooth muscle was identified in the outer portions of the muscular layer (Figure 1). There was thrombosis in several of the vessels and an extensive inflammatory reaction in the vessel walls (Figure 2). Whether this lesion began as an inflammatory reaction, with involvement of vessel walls, thrombosis, and extensive necrosis, or whether a vasculitis was present as the primary lesion is a difficult question. Unfortunately we were unable to culture any organisms usually responsible for this kind of colonic lesion. Intravenous broad spectrum antibiotics were given during hospitalization which may have altered the bacteriology report. There was bilateral renal cortical necrosis and, as usual, there was sparing of the glomeruli in the corticomedullary junction as well as those immediately beneath the capsule. There was thrombonecrosis of afferent arterioles and glomerular capillaries with bright pink fibrinoid material occluding these vessels (Figure 3).

The patient also had minimal acute bronchopneumonia and a minimal but definite acute inflammatory reaction in the leptomeninges of the cere-

---

*Assistant Professor, Department of Pediatrics, University of Minnesota.

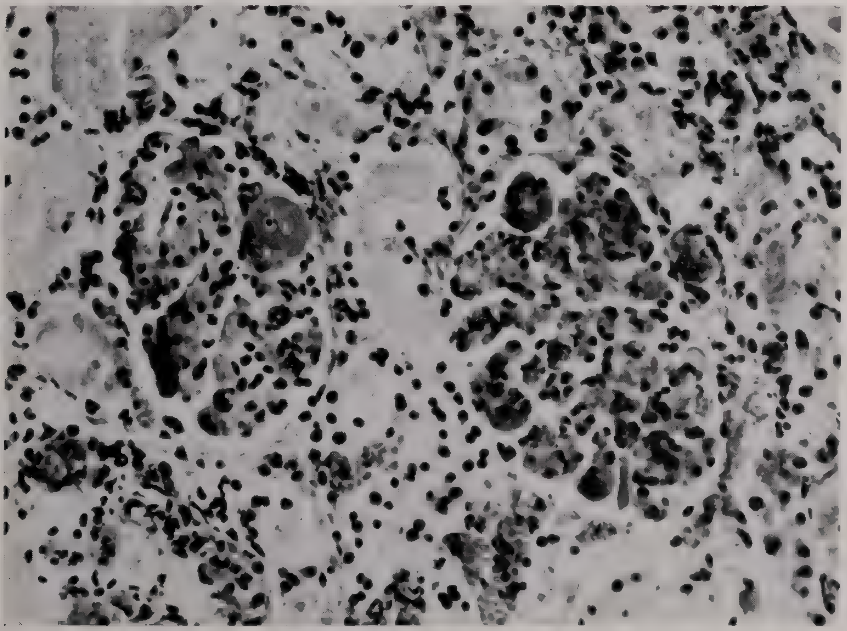

Fig. 3 — This shows deposition of fibrinoid material and early necrosis in the glomerular capillaries. x450

Continued

bral cortex and the cerebellum. Perhaps these lesions were the result of terminal seeding of the blood stream with bacteria. We found no vasculitis in any other organ, and the brain was otherwise entirely normal.

The most likely diagnosis is bilateral renal cortical necrosis, the result of gram-negative bacteremia with terminal pneumonitis and meningitis. The portal of entry for the gram-negative organism may have been the colon, and the disease may have begun as a dysentery.

The usual poisons capable of producing renal cortical necrosis do not seem likely, because of lack of associated lesions in other organs, particularly the liver. Poisons capable of producing necrotic lesions of the gastrointestinal tract do not usually cause renal cortical necrosis but often do cause hepatic and other organ involvement not found in this child. Without a toxicology study, however, we cannot definitely exclude the possibility of poison.

Dr. Good:

I saw two cases in an epidemic pathogenic E coli diarrhea in an army post in Utah which ended in the same way. It doesn't necessarily have to be Shigella infection but can be due to other gram-negative bacteria.

It would be informative to know whether or not immunohistochemical studies would reveal the occluding material to be primarily fibrinogen or primarily gamma globulin. In the hemolytic anemia-uremia syndrome the primary material occluding the vessels appears to be gamma globulin. Fibrinogen is not present here. In the generalized Shwartzman reaction the occluding material is entirely fibrin or fibrinogen.

Early Man Vindicated?

A toad boiled in water, made into a mess like the witch's caldron of Macbeth and given to a man swollen with dropsy, seemed to benefit him. Pure fancy? That is what scientists thought until a few years ago when they discovered that the toad has in its skin a drug called bufonin that may actually be helpful in treating dropsy.

From ancient China came the belief that eating bits of dragons' bones drove away the evil spirit that caused babies to have fits. Foolish as this sounds, dragons' bones were really those of dinosaurs buried in the sands of the Gobi Desert. Today for a certain kind of convulsion that babies may have the doctor prescribes calcium, and the dinosaur bones, like all others, contain calcium!

Would you believe that the ashes from a burnt sponge could help relieve a swelling in the neck? Ashes were used, and they drove away the spirit that caused the swelling — according to the ancient theory. Modern science has shown that a swelling of the neck called a goiter may occur when there is too little iodine in the food and drinking water, as is the case in some parts of our country. Small amounts of iodine are given to prevent goiter. The ashes of sponge contain iodine.

— Haggard, Howard W.: The Doctor in History, Yale Univ. Press, 1934.

Grand Rounds

The Gastrointestinal Manifestations of Scleroderma[*]

NEIL HOFFMAN, M.D.
Medical Resident

> *"To wither slowly, and to be beaten down, marred and wasted until one is literally a mummy incased in an ever shrinking, slowly contracting, skin of steel. . . ." — Sir William Osler*

SCLERODERMA IS a generalized disease of connective tissue involving the skin and various viscera. It was first described by Curzio in 1752 and was recognized as a primary skin disorder.[1] The term scleroderma means "hard skin". Only recently have the systemic manifestations of this disease been recognized. Heredity is not considered significant. Females seem to be involved over males by about 3:1, and adults are usually affected.[1,2] Most cases fall between the ages of 20 to 50, while the highest incidence is noted between 51 to 60 years of age.[1] Early symptoms include swelling and stiffness of the skin, joint tenderness, dysphagia, and vague abdominal complaints.[1,2] There may be hyperpigmentation surrounding the involved skin areas. Articular symptoms are common early in the disease.[3] Sclerosis usually begins in the hands and then spreads to the face and forearms.

Clinical Stages[4]

Edematous (Table 1)

In this stage the skin is tense but appears swollen. It does not pit on pressure, and cannot be folded. Due to the tautness or loss of elasticity, the face assumes a fixed or mask-like expression.

Indurative

In this stage the skin is stiff and firm, as best seen on the fingers. There may be flexion contractures at the fingers, due to tightening of the skin. Hyperpigmentation may be present.

Atrophic

In this stage the finger tips become small and pointed. Mucous membranes become dry and are in part replaced by collagen. Ulcers may develop on these areas, secondary to ischemia and increased tension.

While it seems, in many cases, that scleroderma is confined to the skin, there tends to be a rapid, progressive, systemic involvement that may lead to death, usually from cardiac or renal failure.[5] Due to the generalized involvement of this disease, Goetz[6] in 1945 proposed the more descriptive term, "progressive systemic sclerosis".

Etiology

There have been numerous attempts to establish an etiology for this disease; but though many have been proposed, there is as yet no proof of the cause of scleroderma.

Infection

Scleroderma has been reported following various infections. Tonsillitis, scarlet fever, diphtheria, pneumonia, syphilis and tuberculosis have all been considered responsible.[1] O'Leary[7] thought scleroderma was due to arsenic intoxication, as he noted increased arsenic excretion in the urine of several patients with the disease.

Endocrine

The entire endocrine system has at one time been suspected in the etiology of this disease. Thyroid dysfunction was thought to be important; but O'Leary,[7] in over 150 cases, showed 97 per cent to have normal thyroid function tests. Desiccated thyroid seems to have no effect on the progression of the disease. The parathyroid glands have been suspected because of the calcium deposits that are seen in the skin ulcers; but surgical removal of these glands seems to have no effect on the disease process.[1]

Neurogenic

A neurogenic basis for scleroderma has been suspected because of Raynaud's phenomenon, frequently seen in people with cutaneous scleroderma. Degenerative changes have been noted in the sympathetic nerve fibers in the skin, often preceding any collagen disturbances.[2] Although Raynaud's disease is frequently an early finding in scleroderma, there has been no proven relationship. O'Leary[7] reports that 50 per cent of scleroderma starts as arthritis or as a vasospastic phenomenon (Raynaud's).

Allergy

The allergy theory has never become popular, but there have been new cases of scleroderma following vaccination. Also, there generally is an increase in gamma globulins in scleroderma.[2,7] Walder[8] reports a series of seven patients manifesting symptoms of scleroderma following contact with various organic solvents. There are no specific laboratory findings in the disease; rather they reflect the involvement of various organic systems.

There has been an attempt to classify as a separate disease called acrosclerosis those cases that exhibit Raynaud's phenomenon and cutaneous involvement of the hands and face. Goetz,[6] however, has shown that both scleroderma and acrosclerosis represent a spectrum of only one disease, progressive systemic sclerosis (scleroderma), which may present with a variety of symptoms and manifestations.

Gastrointestinal Involvement

Scleroderma can no longer be classified as a dermatologic disease. Reports have recently been published pointing out the generalized nature of this disease. Autopsy series show the gastrointestinal tract to be involved in about 60 per cent of those individuals having cutaneous manifestations of scleroderma.[9,10,11] The symptoms of gastrointestinal involvement may follow the onset of cutaneous findings from a few months to twenty years.[9,10] Recently reports of gastrointestinal involvement before the onset of cutaneous manifestations have been noted.[4] About 10 per cent of patients with scleroderma show signs of visceral involvement without any cutaneous manifestations.[13] Herrington[12] reports on a patient who presented with symptoms of incomplete obstruction for six years. In this case laparotomy was finally resorted to, establishing the diagnosis of scleroderma. Some four and one-half years following surgery, there was still no evidence of cutaneous manifestations of scleroderma.

Esophagus

Ehrman, in 1903, reported the first case of scleroderma associated with esophageal abnormalities.[13] His patient presented with symptoms of progressive dysphagia. Esophagoscopy showed redness of the mucosa, with generalized thickening and edema. There was scar tissue, with constrictive bands and ulcerations about the lower half of the esophagus.

Esophageal involvement with scleroderma usually produces symptoms of *progressive dysphagia,* first with solid foods, then with liquids. There may be a feeling of fullness after swallowing, or there may be a burning sensation in the epigastric area unrelated to swallowing. Nausea is commonly present. There may also be, as a complicating factor, difficulty in mastication, due to the inability to fully open the mouth.[1,2,10] Such esophageal involvement, when an early manifestation of scleroderma, may unfortunately be disregarded by the physician as a functional complaint.

Some 45 to 90 per cent of patients with scleroderma show changes on x-ray.[10,14,15] The earliest radiographic findings seem to be *diminished*

Continued

peristaltic waves in the esophagus.[27] To appreciate this one should examine the patient in the recumbent position to negate the effects of gravity on the barium meal. Dornhurst[16] has found that by this method one can detect esophageal involvement before clinical symptoms are evident. The primary peristaltic wave normally travels the entire length of the esophagus during deglutition; however, in scleroderma it descends only to about the suprasternal notch.[11,23,30] Cinefluoroscopy shows a *prolonged transit time,* with slight dilatation of the esophagus, but there is usually no evidence of complete obstruction in the esophagus.[13] Food has been noted to remain in the esophagus for more than one hour while the patient is recumbent, but when he assumes an erect position normal rapid transit time is observed. Emptying of the esophagus may depend entirely on gravity.[30] By measuring esophageal pressures, one finds the upper half of the esophagus to have normal contractions and normal transit time, whereas the contractions become feeble or absent in the lower half of the esophagus.[2] There is then a loss of pressure gradient across the cardio-esophageal junction, resulting in reflux of gastric contents, causing esophagitis.[9]

Areas of constriction usually appear a few centimeters above the cardio-esophageal junction, with proximal dilatation of the esophagus.[2,11] (See Figure 1.) Occasionally this picture may be mistaken for achalasia or cardiospasm, the difference being that in scleroderma the lower one third of the esophagus is involved, whereas in cardiospasm, usually only the cardia is involved.

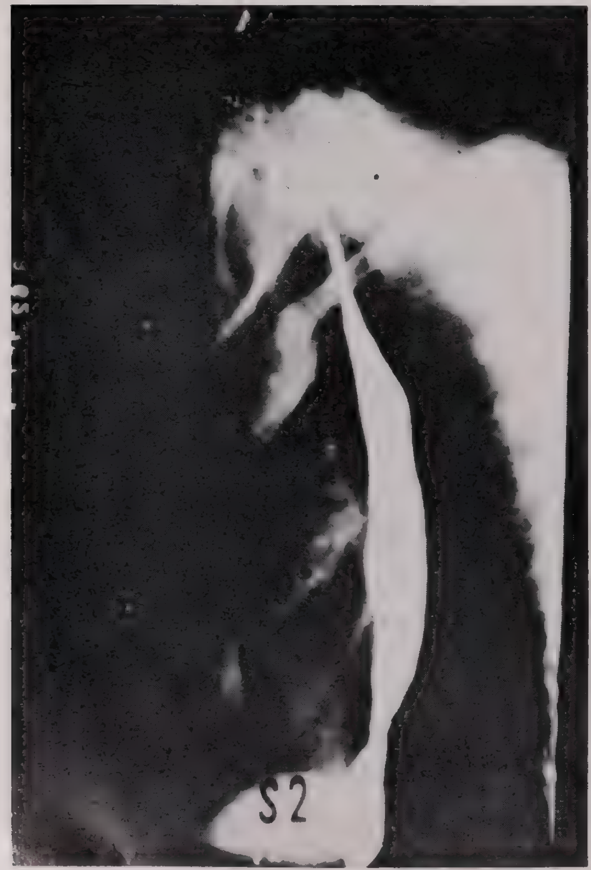

Fig. 1 — X ray # 1.

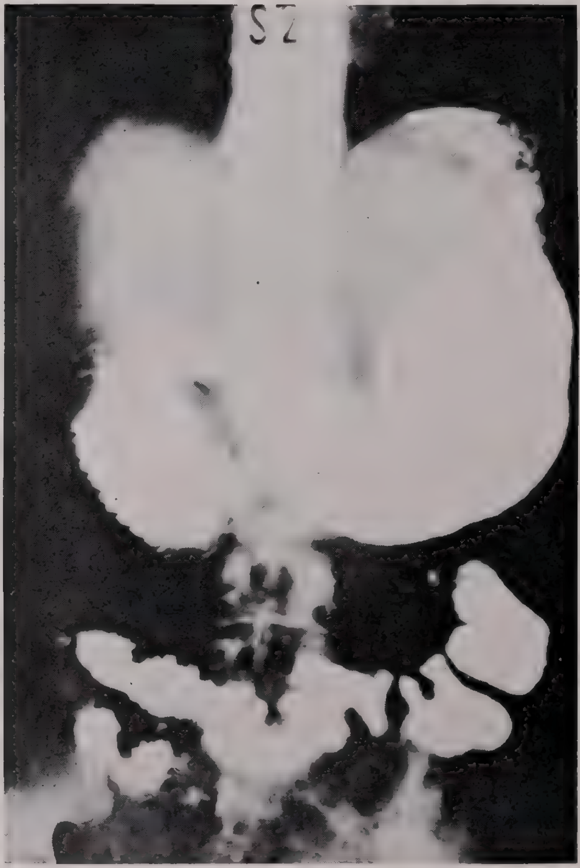

Fig. 2 — X ray # 2.

Pathology

A patchy deposition of an acellular collagenous fibrous tissue has been reported in the submucosal, muscular, and serosal layers.[9,28] It is this deposition that produces the stricture in the lower esophagus, as seen on x-ray, causing rigidity of the lower esophagus with resultant reflux.[4,17] Goetz,[6] in an extensive study, reports one patient who developed a niche at the constricted portion of the esophagus and succumbed. Autopsy showed the submucosa was thickened, with acute and chronic inflammation. He concludes therefore that sclerosis of the connective tissue is a basic feature of this disease process and produces many of the esophageal symptoms. Anderson[18] substantiates this and feels that the resultant atrophy of the muscular layer is likewise a basic pathologic process of esophageal involvement in scleroderma. Also there is a collagenous degeneration of the submucosa. The mesenteric and submucosal ganglia do not appear to be involved, although atrophy of adjacent structures may make them more prominent. Vascular changes of varying degrees may also be present.[6,9,20] One may see mucosal ulcerations, hiatal hernia, or erosions in association with scleroderma; but esophageal perforation is rare.

Stomach

There have been no reported lesions of the stomach with scleroderma.[1] Rake[17] reports dilatation and lymphocytic infiltration in the mucosa, with delay in emptying and spasm in the antral area.[20] Wolfel[21] reports one case that seems to affect the stomach primarily. His patient had narrowing of the gastric antrum that radiographically resembled linitis plastica. Hoerner[15] undertook a study to relate common gastrointestinal diseases to scleroderma. In a review of 724 cases only four per cent had peptic ulcer disease associated with visceral scleroderma. The incidence of peptic ulcer in the general population runs five to ten per cent. Piper,[10] in a series of 31 patients, reported two gastric ulcers. Unlike dermatomyositis, where malignancy is reported to be as high as 20 per cent, there appears to be no increased evidence of gastrointestinal malignancy in scleroderma.[9]

Small Bowel (Tables 2 and 3)

Scleroderma involvement of the small bowel may be more common than was previously thought. There may be small bowel involvement in the absence of esophageal or other visceral involvement.

Recognition of small bowel involvement in scleroderma is relatively recent. In 1962 there were only 67 reported cases, including one by Reinhardt in which 33 cases were reported.[22] Malabsorption seems to be a dominant feature in scleroderma of the small bowel but occurs late in the disease.[5,9,31] Factors causing malabsorption are not well known. There have been reported mucosal infiltration of round cells, as seen in sprue, and these are thought to alter the absorptive capacity of the bowel. Scleroderma can also present as obstruction. Herrington[12] reports a successful result with surgery in a case of scleroderma with small bowel involvement.

Forty-four per cent of patients with scleroderma have small bowel abnormalities,[22] with the duodenum usually involved. The duodenal bulb dilates and retains barium long after the stomach empties. There has been retained barium in the duodenal bulb for as long as 24 hours after ingestion.[6,22,23] (See Figure 2.) Large dilated loops may mimic intestinal obstruc-

Continued

tion. Dilatation of the second and third portion of the duodenum is quite constant in scleroderma.[23] In the jejunum there seems to be flocculation of barium as well as isolated dilated loops. The mucosa is thickened and irregular, and there is delayed transit time through the small bowel.[22] Reinhardt has found small bowel involvement in the absence of esophageal findings (Table 4).

Microscopic Pathology

As in parts of the gastrointestinal tract, so there is atrophy also of the muscle layers with irregular replacement by collagen fibers. The villi are atrophic. Haskins[9] describes a "ceroid" pigmentation in the smooth muscle, the significance of which is not known, but which is thought to represent a vitamin E deficiency, probably secondary to malabsorption. Rossom[24] did peroral duodenal biopsies in six patients with scleroderma and found that Brunner's glands were incased in collagen and that the muscular elements were atrophied and fragmented. The glands themselves were

normal, the deposition of collagen around them probably occurring early in the disease.

Large Bowel

Involvement of the colon by scleroderma produces decrease in motility. The colon may become atonic and constipation may occur.[9,11] Radiographically, there may be loss of haustral markings, shortening of the involved bowel, and a picture similar to ulcerative colitis. Heinz[23] reports that 53 per cent of patients with large bowel involvement have diverticula, differing, however, from the normal colonic diverticula which are globular in appearance and have narrow stalks. The diverticula seen in scleroderma are saccular, wide-mouthed, and occur mainly in the transverse colon. These patients seem to tolerate surgery poorly and the mortality with resection is high. Cullinan[26] describes the sigmoidoscopic changes as showing pale, dry mucosa. Only rarely does the mucosa undergo ulceration; but when it does occur, it is thought to be the result of ischemia rather than of infiltration and sclerosis.

Liver

The liver is rarely reported as being involved in scleroderma. One series,[27] however, comprises 727 patients, eight of whom had signs of hepatitis. Liver biopsy shows changes resembling post-necrotic cirrhosis.

Experience at Hennepin County General Hospital (Table 4)

During the ten-year period, 1954 to 1965, there have been six new cases of scleroderma diagnosed at this hospital. Our incidence of females to males is 5:1, in comparison to 3:1 in most series. Four of our patients had symptoms in their extremities compatible with Raynaud's disease; five had dysphagia, with radiographic abnormalities suggesting scleroderma. Only one patient had small bowel involvement on x-ray, consisting of dilatation of the second and third portion of the duodenum, as well as dilated areas of the jejunum, with an abnormal mucosal pattern. We have had no cases in which the gastrointestinal manifestations preceded cutaneous involvement. This is probably due to a low suspicion of the visceral aspects of this disease. One must examine patients with visceral complaints that include dysphagia, in the recumbent position; otherwise, early cases of scleroderma

Continued

will be missed. The decrease or loss of peristaltic activity in the lower esophagus should make one suspect scleroderma.

Treatment

As of now, there is no satisfactory treatment for scleroderma. Therapy has generally been disappointing, because we do not know the etiologic basis for this disease or understand fully all of its manifestations. Past treatment has included thyroidectomy, parathyroidectomy, sympathectomy, x-ray, ultra sound, posterior pituitary extract, antibiotics, antisyphilitic agents, vitamins, chelating agents, and steroids.[9,14,23] Also symptomatic treatment for the gastrointestinal symptoms has been used. Urecholine may be beneficial in selected cases where motility is bothersome. Evans reports relief of dysphagia by thoracic sympathectomy; but the x-ray picture remains the same following surgery. Steroids have generally proved disappointing. They seem to be more effective in managing the articular and cutaneous manifestations.

Summary

Scleroderma should be thought of as a disease affecting many organ systems with protean manifestations. Probably the term proposed by Goetz, of progressive systemic sclerosis, is a more meaningful term and should be used in discussing this entity. Symptoms depend on the tissues involved. The disease process may be fulminant or remain in an arrested state. Its course is usually marked by periods of exacerbations and remissions. There is no curative therapy. Symptomatic treatment is beneficial. Steroids seem to have some value but are most effective on the articular manifestations.

Case Report

A 45-year-old white female first came to this hospital in 1959. At that time she had mild cutaneous involvement about the hands and a two-week history of dysphagia. Skin biopsy was done, the results being compatible with scleroderma. Previous hospitalization included a ruptured appendix and Lannec's cirrhosis. Her course has been stable with episodic exacerbations of her disease.

She was hospitalized in April 1965, with progressive dysphagia, arthritis, and vasospastic changes in the upper extremities. The skin over her hands, face, and neck was taut, smooth, and velvety. Her liver was enlarged three to four centimeters below the costal margin. She had metacarpal swelling, with marked ulnar deviation of both hands. The deep tendon reflexes showed a prolonged relaxation phase.

Laboratory Data

X-Ray: An upper G.I. series, taken on April 23 1965, shows a stricture in the distal esophagus, with lack of peristaltic activity. The stomach and duodenum were moderately dilated, and there was loss of the normal jejunal mucosal pattern. A barium enema showed diverticula in the mid portion of the descending colon.

ECG. was normal. L.E. prep was normal on three different determinations. PBI. was 4.9 micrograms per cent. BUN. creatinine, BSP. and the Papanicolaou's smear were within normal limits. F.A.N.A. was positive in a 1:10 dilution.

She was treated symptomatically with partial remission of her symptoms.

Advances

Antibacterial Management of Infections Due to Gram-Negative Bacilli[*]

Part I. Introduction, Pathogens, and Use of Streptomycin, Dihydrostreptomycin, Neomycin, Kanamycin and Gentamicin

WILLIAM J. MARTIN, M.D.[**]
Rochester, Minnesota

EXPERIENCES WITH infections due to gram-negative bacilli have been reported periodically by members of our group. During the last 25 years, an increasing incidence of serious infections due to these bacilli has been observed.[1-9] With the availability of effective antibacterial agents, greater effort is expended at diagnosing these infections, but one hesitates to attribute the increase to this alone. Perhaps of more significance is the emergence of an expanding group of individuals susceptible or predisposed to infection due to gram-negative bacilli. In this regard, antimicrobial control of other infections that formerly caused death may have preserved more candidates for ultimate invasion by gram-negative bacilli. Also, there are diseases of increased incidence in an aging population, such as diabetes mellitus, malignant neoplasms, and cirrhosis, which possibly predispose to gram-negative bacillary infections. In addition, there are modern therapies that prolong life in patients with limited ability to resist infection, and some, such as adrenal glucocorticoids, radiation, and radiomimetic therapy as well as antimicrobial therapy itself, that may alter or bypass defense mechanisms of the host. An important pathogenic factor appears to be the use of surgical and instrumental procedures whereby invasion with gram-negative bacilli is facilitated. It is evident that multiple factors may be involved in the increasing incidence of these infections.

Pathogens

Among the gram-negative microorganisms, there are the gram-negative bacilli. When one concerns himself solely with the latter bacteria, he thereby excludes from consideration the group of cocci referred to as Neisseria (Table 1). He also removes from consideration the spirochetes or spiral microorganisms which, while often difficult to stain by the Gram method, are usually gram-negative when they accept the stain. Also excluded are the *Mycoplasma* and *Rickettsia.* As a therapeutic consideration, infection due to Neisseria and spirochetes or spiral microorganisms are generally managed with such antimicrobial agents as penicillin, employed against gram-positive cocci. However, in pneumonitis due to *Mycoplasma pneumoniae* or in rickettsial infections, one uses antimicrobial agents such as a tetracycline, which are often employed against gram-negative bacilli.

Also in restricting a discussion to gram-

[*] The six parts of this paper were presented, in part, at the Symposium on Antibacterial Agents sponsored by the Southern California Society of Hospital Pharmacists, Los Angeles, California, May 2, 1965.

[**] Mayo Clinic and Mayo Foundation: Section of Medicine.

negative bacilli, one obviously excludes from consideration the gram-positive bacilli. Infections due to organisms of Mycobacterium require rather specialized therapeutic regimens, but the management of tuberculosis includes the use of streptomycin, which is employed against gram-negative bacilli. Antimicrobial agents, such as penicillin, which are often employed against gram-positive cocci, have been effective in cases of gas gangrene, diphtheria, anthrax, listeriosis, and erysipeloid. *Lactobacillus* and *Bacillus subtilis* organisms rarely warrant therapeutic consideration.

Excluding gram-negative microorganisms other than bacilli and gram-positive bacilli from our discussion, the major "gram-negative bacilli" can be considered (Table 2). Among the Enterobacteriaceae are the coliform bacilli which include *Escherichia coli,* the *Klebsiella-Aerobacter-Serratia* group and the *Paracolobactrum* or paracolon bacilli. In addition to the coliform bacilli, organisms of *Proteus, Alcaligenes, Salmonella,* and *Shigella* also occur in the intestinal tract. The use of intravenously administered penicillin G in doses of 20 to 60,000,000 units/day has been suggested in infections due to Enterobacteriaceae, excepting *Proteus* organisms. *P. mirabilis* may be sensitive to more orthodox penicillin dosage, whereas *Proteus* organisms that are indole-producing *(P. vulgaris, P. rettgeri, P. morganii)* are resistant to even such a heroic dose. In patients allergic to penicillin who have infections due to *P. mirabilis,* other drugs which may be considered include erythromycin and novobiocin. Because other effective drugs are available, there probably is no need of frequent penicillin therapy for infections due to Enterobacteriaceae, except for some of those due to *P. mirabilis.* In this regard, massive doses of penicillin have been recommended in the management of carriers of *S. typhosa.* Of the Enterobacteriaceae, *E. coli, Klebsiella-Aerobacter,* and *Proteus* organisms are encountered most often in routine medical practice.

Pseudomonas organisms and members of the Bacteroidaceae may have enteric residence but are not classified as Enterobacteriaceae. Polymyxin B or colistin is employed in serious infections due to *Pseudomonas* organisms, and such bacilli are vir-

TABLE 1

Some Microorganisms to be Distinguished
From the Gram-Negative Bacilli

Gram-negative microorganisms other than bacilli
1. *Neisseria*
   - *N. meningitidis*
   - *N. gonorrhoeae*
   - *N. flavescens* (pigmented, rarely causes meningitis or endocarditis)
   - *N. catarrhalis* } (members of respiratory flora)
   - *N. sicca* }
2. Spirochetes or spiral microorganisms:
   Treponema pallidum, *Spirillum minus*, *Leptospira*
3. *Mycoplasma* (PPLO)
4. *Rickettsia*

Gram-positive bacilli
1. *Mycobacterium*
2. *Clostridium*
3. *Corynebacterium*
4. *Bacillus anthracis*
5. *Listeria monocytogenes*
6. *Erysipelothrix insidiosa*
7. *Lactobacillus*: *L. acidophilus* (Moro's bacillus)
   N.B. Boas-Oppler bacillus (of gut) and Döderlein's bacillus (of vagina)
8. *Bacillus subtilis* (member of skin flora, rarely pathogenic)

tually always sensitive to these toxic drugs; however, sometimes *Pseudomonas* organisms are sensitive to other drugs such as streptomycin, the tetracyclines, and the sulfonamides, which may have use if the clinical situation and the in-vitro data allow. As a therapeutic consideration, a tetracycline is preferred in the management of serious infections, such as bacteremia due to *Bacillus fragilis* or the necrobacilli. However, in infections due to fusospirochetes and in the bacillary form of rat-bite fever and Haverhill fever, which are caused by *Streptobacillus moniliformis,* penicillin is recommended. The fusospirochetal diseases include gingivostomatitis (trench mouth), pharyngitis (Vincent's angina), vulvovaginitis or balanitis, lung abscess which may progress to pulmonary gangrene, and rarely bacteremia.

Infections such as brucellosis, plague, and tularemia respond to streptomycin and to a tetracycline but, in infections due to *Pasteurella multocida,* penicillin is preferred.

Among the members of the *Haemophilus* genus, *H. influenzae* is a cause of meningitis, otitis, mastoiditis, endocarditis, and pneumonia, which may be primary or secondary to viral disease. *H. parainfluenzae* and *H. parahaemoliticus* are rare causes of endocarditis. *H. aegyptius,* the so-called Koch-Weeks bacillus, causes conjunctivitis while *H. ducreyi* is the cause of chancroid. *H. vaginalis* is a disputed cause of vaginitis. *H. aphrophilus* is rarely responsible for such infections as endocarditis, brain abscess, and pneumonia.[10] The pathogen responsible for pertussis is more properly referred to as *Bordetella pertussis.*

Organisms of the *Achromobacter* genus infrequently cause serious infections, such as bacteremia. The Mimeae tribe of organisms includes the species *Mima polymorpha, Herellea vaginicola,* and *Colloides anoxydana.*[11] These pleomorphic gram-negative rods are progressively attaining recognition as pathogens and may be confused with other bacteria, including *Neisseria* and *Haemophilus.* Infections said to be caused by Mimeae include conjunctivitis, vaginitis, urethritis, bacteremia, endocarditis, and meningitis. Infection due to *Vibrio fetus* resembles brucellosis in its pathogenesis and symptomatology and has been managed by a similar regimen. Whether the tetracyclines are useful in cholera is disputed; some workers believe replacement of fluid and electrolytes to be sufficient. This latter conclusion might tend to

corroborate the theory that symptoms of cholera may be due more to a toxin produced by the bacteria than to a more direct effect of the pathogen. *Actinobacillus mallei* causes glanders, and a sulfonamide is recommended.

Antibacterial Agents

In the management of infections due to gram-negative bacilli, the antibacterial agents listed in Table 3 have current or potential application. Data on the individual drugs will be presented in detail. It is obvious that drugs such as penicillin, erythromycin, and novobiocin which, as previously noted, may have use in the management of some infections due to gram-negative bacilli are not included, since their usual application is in infections due to other pathogens.

Streptomycin and Dihydrostreptomycin

Ototoxicity

Streptomycin is less likely to produce hearing loss than is dihydrostreptomycin or a combination of the two substances. Dihydrostreptomycin has produced deafness even after use of the drug has been stopped. It is recommended currently that dihyrostreptomycin be used only when the patient needs such an agent and can accept dihydrostreptomycin but not streptomycin. While streptomycin may damage vestibular function of the eighth cranial nerve, this is not so calamitous as deafness, and the dysequilibrium may be compensated, at least partly, by ocular mechanisms. Ototoxicity is best detected if audiometric and vestibular turning tests are done periodically during treatment and thereafter. The evidence of ototoxicity usually parallels the daily dose and duration of streptomycin therapy. The likelihood of ototoxicity is greater in infants, the aged, and those with impaired renal function. As a generalization, in normal adults, ototoxicity is unlikely if 2 gm. or less of streptomycin is given daily for no longer than 14 days, or 1 gm. is administered daily for four weeks or less. The blood concentration of streptomycin should not exceed 25 μg./ml., and the daily dose should be adjusted accordingly. A 0.25 to 0.5-gm. dose of streptomycin given every two to four days may suffice in the azotemic patient.

Concentrations of streptomycin in the perilymph may exceed those in the spinal fluid and may persist longer; also there may occur accumulation of the drug in the perilymph so that regular administration may further increase the concentration of streptomycin therein. Serum levels of the drug exceed concentrations in both the perilymph and spinal fluid. The relationship of the drug's concentration in the perilymph to the ototoxicity of streptomycin currently is conjectural.

In Pregnancy

With the exception of streptomycin, there is little exact evidence of fetal damage from administration of antibacterial agents to a pregnant woman, although other drugs appear to freely traverse the human placenta. There are reports of ototoxic residua in children born to mothers receiving streptomycin. Untoward effects of the tetracyclines, chloramphenicol, novobiocin, and the sulfonamides are such that one should appraise their use in pregnant women as perhaps being potentially hazardous to the fetus. The tetracyclines may form a calcium complex with the fetal skeleton and the de-

veloping deciduous teeth; chloramphenicol may cause the fatal "gray syndrome" especially in premature infants, while novobiocin and the sulfonamides may adversely affect maternal and neonatal bilirubin metabolism. In premature infants this effect of the sulfonamides may increase their susceptibility to kernicterus.

It is not definitely known if prior use of streptomycin or other ototoxic drugs like kanamycin increases the chance of ototoxicity on future use of streptomycin, but this possibility should be considered when the drug is administered. In any event, ototoxic drugs should not be used concurrently.

Curariform Action

Streptomycin,[12] dihydrostreptomycin, neomycin, kanamycin, polymyxin B, and colistin share a potential curariform action which may produce neuromuscular block and respiratory arrest,[13] especially on intracavitary instillation. Such an effect would be unusual when streptomycin is given intramuscularly; but the possibility is considered in infants, the aged, patients with renal disease or hypoxic states, and those receiving drugs such as muscle relaxants, sedatives, narcotics, and anesthetic agents. In patients having such an untoward reaction, use of neostigmine or calcium may be helpful. The previously mentioned antibiotics are contraindicated in patients who may have myasthenia gravis.

Other Undesireable Reactions

Optic neuritis may follow the administration of either streptomycin or chloramphenicol and is a theoretic reason for avoiding concurrent use of these drugs.

Fever, rashes, paresthesia, headache, and rarely pericarditis may result from the use of streptomycin.

Indications

Currently, streptomycin is used mainly in combined therapy, as with penicillin in management of enterococcal endocarditis and with a tetracycline in treatment of such conditions as brucellosis or pneumonia due to *K. pneumoniae*. Incidentally, the antienterococcal effect of combined streptomycin-penicillin therapy may be the best clinical example of an enhanced antibacterial effect. Use of streptomycin against tuberculosis along with other agents hardly requires reiteration. Tularemia is one of the few diseases in which streptomycin currently is employed alone with good results.

Neomycin

Intramuscular use of neomycin (Mycifradin) has decreased, especially since the advent of kanamycin. Neomycin, like kanamycin, has limited anticoccal action, and generally this is chiefly antistaphylococcal; in addition it is effective against strains of Enterobacteriaceae. Bacterial resistance to neomycin has increased in recent years, perhaps because neomycin is incorporated in procedures used to prepare the colon before the operation, and also because the drug is a constituent of numerous preparations for local use, such as sprays and creams. In this regard, neomycin, kanamycin, and paromomycin may be cross-resistant, and there is partial bacterial cross-resistance among these drugs and streptomycin.

Indications

Because of its potential nephrotoxicity and neurotoxicity when administered systemically, neomycin is reserved principally for (1) topical application, (2) preoperative preparation of the colon, and (3) certain cases of hepatic coma. It has also been given orally, both alone and with polymyxin B in cases of enteric salmonellosis and shigellosis.

Contraindications

Since neomycin is not absorbed well from the intestine, as much as 8 to 12 gm. has been given daily by the oral route in certain patients, such as those with hepatic coma. Preferably, no more than 4 gm. orally per day should be given, especially in patients with hepatic or renal disease, because blood concentrations may become so high as to induce toxic effects. If neomycin is given intramuscularly, a daily dose of 1 gm. should not be exceeded.

Neomycin-induced *ototoxicity* principally

Continued

involves auditory function and is irreversible. It has occurred after the drug has been used orally, intramuscularly, as an aerosol, and after topical application to cutaneous burns.

In addition to neomycin, there are five drugs that can cause *paresthesias*, usually circumoral and of the acral parts; these same drugs are capable of a curariform effect and are streptomycin, dihydrostreptomycin, kanamycin, polymyxin B, and colistin.

Malabsorptive Effects

Malabsorptive effects on oral use of neomycin may resemble those of nontropical sprue and include steatorrhea, azotorrhea, and interference with the absorption of vitamins, sugars, and minerals, as well as small-bowel alterations on biopsy. Neomycin-induced malabsorption may be the basis for the hypocholesterelemic effect that occurs after the drug is used orally.

Contact dermatitis from local use of neomycin occurs.

Neomycin, streptomycin, the tetracyclines, and other drugs may depress the gram-negative elements of the normal flora and allow overgrowth of resistant staphylococci. Bacteremia, pneumonia, and other staphylococcal superinfections may occur in addition to staphylococcal enterocolitis.

Kanamycin

The antibacterial spectrum of kanamycin (Kantrex) closely resembles that of neomycin. Kanamycin has use against staphylococci and strains of *E. coli*, *Klebsiella-Aerobacter*, *Proteus*, *Salmonella*, and *Shigella*, but it is not active against all *Pseudomonas* organisms and usually is ineffective against streptococci, pneumococci, and *Bacteroides* organisms. Organisms show almost complete cross-resistance to neomycin, paromomycin and kanamycin as well as one-way cross-resistance to streptomycin and kanamycin or the other drugs; that is, organisms resistant to kanamycin are resistant to streptomycin, but organisms resistant to streptomycin may be sensitive to kanamycin.

The daily intramuscular dose for an adult of average weight is 1.0 gm. and should not exceed 1.5 gm., even for heavier patients. Rarely is kanamycin given intravenously.

Injection of kanamycin directly into the gallbladder during laparoscopy in the management of typhoid carriers has been recommended when less heroic measures have failed.

Ototoxic Effects

One should be hesitant to continue therapy beyond 10 days because of the drug's capacity to cause deafness which may be delayed in onset and is irreversible. Other untoward effects include rashes, fever, nephrotoxicity, curariform action, paresthesia, and superinfection.

In addition to kanamycin, there are at least five other potentially ototoxic drugs: streptomycin, dihydrostreptomycin, neomycin, gentamicin[13] and vancomycin. Whether ristocetin or colistin is ototoxic is uncertain. One should avoid concurrent and perhaps sequential use of these ototoxic drugs.

Gentamicin

Gentamicin (Garamycin) is available only for investigational use. The antibacterial spectrum and toxicity of gentamicin resemble those of neomycin and kanamycin, but gentamicin may be more effective against *Pseudomonas* organisms. Gentamicin is poorly absorbed from the gastrointestinal tract and for systemic effect is given intramuscularly. Adults have received a total daily dose of 50 to 100 mg., given in two or three intramuscular injections for as long as 10 days. However, the drug has been used successfully by the oral route in enteric infections and on intramuscular injection in urinary infections.

Vestibular damage, which may be of delayed onset is the chief hazard of gentamicin therapy. Of the ototoxic drugs, streptomycin and gentamicin are more likely to cause vestibular damage, whereas dihydrostreptomycin, neomycin, kanamycin, and vancomycin are more likely to induce deafness.

Other untoward effects include nephrotoxicity, increased serum glutamic oxaloacetic transaminase activity, superinfection, fever, and rashes.

Abstracts, Briefs and Commentaries

INTRADUCTAL PAPILLOMA OF THE BREAST

"A discharge from the nipple must always, except during pregnancy or lactation, be considered a sign of a disease in the underlying mammary tissue, regardless of whether the discharge is serous, serosanguineous, or hemorrhagic*." The most common cause is an intraductal papilloma, but as a rule it co-exists with other changes of glandular tissue. When a mass or lump is also palpable, the percentage of carcinoma increases.

Judd reported 100 patients with this sign, 57 per cent of whom had cancer. All patients with cancer had a palpable lump. Bloodgood found that of patients with a nipple discharge without a palpable lump, only one per cent had cancer. Among 108 patients with bleeding nipple, Adair found malignancy in 47 per cent and, supported by Cheatle and Cuttler and by Kaal, expressed the opinion that papillomas might become adenocarcinomas. In a series of 87 patients with bleeding nipple and a malignant tumor, Gray and Wood found 60 per cent to have no palpable changes. They make a distinction between two types of papillomatous tumors of the breast, viz., benign intraductal papilloma, fairly common, and malignant, papillomatous carcinoma. The validity of their histological diagnoses has been questioned by Haagensen et al. Saltztein and Pollock found no malignant tumors among a series of patients with bleeding nipple only, while several others reported from two to twelve per cent.

There are different views expressed on the type of treatment. Local excision with meticulous care is described by Haagensen with but two recurrences in five years of follow-up. However, a simpler method advocated by Babcock, who advises the excision of a wedge of the breast including the whole duct, is not only technically easy but gives a good cosmetic result.

The authors report 80 Babcock resections on 77 patients. All had nipple discharge and 14 a palpable tumor. Sixty per cent had their operation within six months of onset of bleeding and 70 per cent within the first year. Thirty-five patients underwent surgery before their menopause and 36 after. The majority of these patients were between 40 and 55 years of age, while the preponderance of malignant tumors occurred in women between 60 and 65 years of age.

Mammography was done on 69 operated patients prior to surgery, with

Continued

2.8 per cent considered failures: a far cry from the statistics of the Houston group. In 44 cases, however, mammography gave a suspicion of intraductal disease.

Among 14 patients with a palpable mass, four had cancer; of the entire group, 10 had cancer. Their follow-up is inadequate for conclusions in view of the small number of patients, the brevity of time, and the number who have not returned for examination.

The authors conclude definitely that all patients with discharge from the nipple, serous or hemorrhagic, should be subjected to surgical treatment because of the possibility of malignancy.

ANASTOMOSIS BY GLUING

Several drops of surgical adhesive (Eastman 910 Monomer) were placed between the overlapping bowel edges in doing experimental anastomosis on a dog's intestines. These studies were conducted on both the large and small gut, and a comparable series of controls by standard suture methods were used.

After removing about one inch of mucous membrane from the distal loop, the proximal loop was pulled into the denuded area with sutures. The tissues were then glued together and the sutures removed.

Though the authors do not suggest that the method is yet clinically applicable, they believe that it offers enough potential to warrant further investigation. In their dog experiments they obtained good results in a very high percentage of the cases.

Editor's Note: This is a new procedure which deserves watching.

CIRRHOSIS AND VARICES

A group organized to study diseases of the liver followed 471 patients with cirrhosis and esophageal varices at 7 co-operating hospitals. Only 8% of the 471 had had prior hepatitis while 83% of these patients were alcoholic, 96% had jaundice, ascites, or hepatic pre-coma singly or in combination, and 51% had massive upper gastrointestinal bleeding. The major causes of death were hemorrhage in 34%, hepatic failure in 32%, renal shutdown in 11% and infection in 9%. Despite vigorous treatment, survival 1 year after demonstration of varices was only 34%, and the survival curve for this group almost duplicates the curves obtained by Ratnoff and Patek in their analysis of patients with decompensated cirrhosis who entered 5 New York hospitals in the years 1938-1961. Reasons are suggested for the failure of improvement in survival despite the acknowledged advances in the understanding and treatment of cirrhosis and its complications.

NEUROTICISM AND HYPERTENSION

This report examines the hypothesis that hypertension is a psychosomatic illness. Neuroticism, defined as emotional over-responsiveness and a tendency to break down under stress, and extroversion, defined as a tendency to be outgoing and sociable, were measured on the Maudsley Personality Inventory (MPI), which was given to four groups of patients. The first group, 459 patients, had psychosomatic disorders; the second group, 231 patients, had possible psychosomatic disorders; the third group, 116 patients, had neurotic disorders; and the fourth group, 546 patients, were normal controls.

The following psychosomatic disorders were associated with a significantly elevated neuroticism score: dysmenorrhea, urticaria, leukorrhea, fungus infections, alopecia, asthma, eczema, menorrhagia, irregular menstruation, seborrhea, dermatitis, psoriasis, hypertension, diabetes, dermatosis, chronic nasal infections, thyrotoxicosis, and rheumatoid arthritis. Psychosomatic conditions not associated with significantly elevated neuroticism scores included peptic ulcer, pruritus, acne vulgaris, and coronary artery disease. In the 19 hypertensive patients the mean level of neuroticism was significantly higher than in the normal controls and it was also significantly higher than in the 67 patients who had chronic organic disabilities resulting from poliomyelitis, cancer, and congenital abnormalities. The extroversion scores of the hypertensive patients were significantly lower than those of the controls. Patients diagnosed as neurotic naturally had higher neuroticism scores than did patients diagnosed as having psychosomatic conditions, and, conversely, patients with illnesses considered to be possibly psychosomatic in origin (cervical erosion, herniated discs, obesity, sterility, etc.) had lower neuroticism scores than patients in the psychosomatic-illness group. Interestingly, patients with heart ailments other than hypertension (including rheumatic valvular heart disease and coronary artery disease) did not have elevated neuroticism scores. These findings suggest that emotional illness did not result from hypertension but that it was a possible causal element in the development of hypertension. From this investigation it appears that patients with psychosomatic illnesses, and especially with hypertension, are intrinsically more neurotic, more emotionally labile, and have a greater propensity to break down under stress than people without hypertension.

MISSED APPENDICITIS: A CONTINUING DIAGNOSTIC CHALLENGE

In spite of advances in diagnosis, recognition of appendicitis often becomes a major problem. An estimated 200,000 cases are recognized in the United States each year associated with an over-all mortality of one per cent. Perforation with abscess and peritonitis is the most important factor. The authors report about one in six to have this complication, which definitely increases the mortality when accompanied by co-existing disease and when encountered in the very young, the very old, and pregnant women. Effort to prevent perforation of the appendix means early diagnosis and oper-

Continued

ation within 36 to 48 hours. The authors review the classical symptoms of epigastric pain, nausea or vomiting, local tenderness, fever, and leukocytosis. Features suggesting appendiceal rupture are: duration of symptoms longer than 48 hours, elevation of temperature to 103°+, physical signs of peritonitis, and a leukocyte count of 20,000. General peritonitis after rupture of the appendix is not inevitable. However, a pelvic abscess without other characteristic features due to perforation of a pelvic-lying appendix is easily overlooked and therefore one of the most dangerous conditions in the abdomen. The mortality rate is about 12 per cent in spite of modern methods of treatment.

A very extensive report of missed appendicitis in a student follows: He had fatigue, malaise, chills, and a temperature of 105°. He also had symptoms of upper respiratory infection and vomiting, for which he was treated by his local physician, with improvement on antibiotics. Later he developed lower abdominal pain, fever, and diarrhea; and during about three weeks he lost 21 pounds in weight. At this time he was admitted to a hospital under the care of the Cleveland Clinic. Complete examination revealed no rebound tenderness and no pelvic mass. Laboratory examinations were negative; however, x-ray studies revealed a large pelvic abscess. He improved on management with tetracycline, 250 mgm. four times daily for two weeks, and was discharged.

The diagnostic dilemma of a long-standing appendiceal abscess (missed appendicitis) may be difficult to resolve, but the therapeutic dilemma may be even more of a problem.

Crile states that an appendiceal abscess can be treated conservatively with antibiotics. Other surgeons have agreed that after an abscess has developed, treatment with antibiotics is as successful as surgery. If the symptoms of an appendiceal abscess are recognized early, most investigators continue to recommend operation. The importance of early diagnosis of appendicitis and appendectomy is emphasized.

Comment

The operative mortality quoted here seems unduly high unless all complicated or missed diagnoses are included. Drainage of a pelvic appendiceal abscess via an abdominal incision has a definite hazard. The drainage via the rectum of an abscess in direct contact with it seems to have been forgotten. Before antibiotics we found it to be a very safe procedure. Evidently the review of the early symptoms of acute appendicitis may be timely.

Ptolemy VII

Ptolemy VII was one of the fattest men of antiquity who was so obese that he could not walk unless supported from both sides. Another tiny tot of antiquity was Denys of Heraclea, who was so fat that he hardly dared to go to sleep for fear of suffocation. To keep him awake it was necessary to place needles in the back of his chair so that he would immediately be awakened as soon as he became relaxed.

— F. William Saul, M.D.: Pink Pills for Pale People

. . NOTHING, THAT IS,
EXCEPT THE SEDATIVE-ANTISPASMODIC
BENEFITS OF

DONNATAL®

There's nothing quite like a vacation to ease the pressures of the modern, "workingday" world. And for the patient who can't get away from it all, there's nothing quite like Donnatal to relax stress-induced smooth muscle spasm. For 31 years it has been the antispasmodic-sedative most often prescribed for relieving functional disturbances of tone and motility of the gastrointestinal tract.

belladonna alkaloids in optimally balanced ratio

In Donnatal, natural belladonna alkaloids are rationally balanced in a specific, fixed ratio that provides "the greatest efficacy with the smallest possible dose."[1] They avoid the clinical uncertainties of the variable tincture and extract of belladonna, and are considered superior in range of action to atropine alone.[2] Furthermore, they are generally recognized as being more effective than the synthetics for relieving visceral spasm.

phenobarbital for sedation

Years of clinical use have established phenobarbital as one of the most efficient and highly regarded sedatives. In fact, for general sedation it is the drug of choice.[3] In Donnatal, phenobarbital potentiates the spasmolytic effects of the belladonna alkaloids, lessening emotional tensions and checking the neurogenic impulses that trigger GI disorders.

more than 24 indications in PDR

Donnatal has withstood the test of time to become the classic sedative-antispasmodic because of its unsurpassed effectiveness, safety, economy, uniformity of composition, and dosage convenience. Its widespread acceptance and usage by the profession can also be attributed to its versatility in treating disorders characterized by smooth muscle spasm. There are more than two dozen distinct and separate indications for Donnatal listed in the current PDR.

IN EACH TABLET, CAPSULE, OR
(5 cc.) OF ELIXIR

hyoscyamine sulfate	0.1037 mg.
atropine sulfate	0.0194 mg.
hyoscine hydrobromide . . .	0.0065 mg.
phenobarbital	(1/4 gr.) 16.2 mg.

(warning: may be habit forming)

IN EACH EXTENTAB

hyoscyamine sulfate	0.3111 mg.
atropine sulfate	0.0582 mg.
hyoscine hydrobromide . . .	0.0195 mg.
phenobarbital	(3/4 gr.) 48.6 mg.

(warning: may be habit forming)

BRIEF SUMMARY: Blurring of vision, dry mouth, difficult urination, and flushing or dryness of the skin may occur on higher dosage levels, rarely on usual dosage. Administer with caution to patients with incipient glaucoma, or urinary bladder neck obstruction. Contraindicated in acute glaucoma, advanced renal or hepatic disease, or a hypersensitivity to any of the ingredients.

Book Reviews

"There can be nothing so gratifying to an author as to arouse the respect and esteem of the reader. Make him laugh and he will think you a trivial fellow, but bore him in the right way and your reputation is assured." — William Lyon Phelps

NEURO-OPHTHALMOLOGY — **(Vol. II) Symposium of the University of Miami, Edited by J. L. Smith, M.D., C. V. Mosby Company, St. Louis, 278 pages, chapter references, index, illustrated — price $21.75.**

This book covers in detail selected topics of current interest to the contributors. Thus, rather than being a comprehensive text, it serves as an excellent source of information and references on the topics presented and would be of use to several specialties.

Chapter 1 by J. L. Smith, M.D., emphasizes the importance of the pupillary reactions and T.P.I. test in detecting seronegative syphilis. In Chapter 3, D. G. Cogan, M.D., has divided heredodegenerations of the retina into four anatomic categories based on the cell areas involved until they can be classified biochemically. This has been possible so far in only several of the many syndromes. E. W. D. Norton, M.D., presents his interesting work on fluorescein angiophotography of the fundus. This has shed light on the differential diagnosis of fundus lesions which are mistaken for malignant melanoma as well as on diabetic retinopathy. The test is clinically applicable using a modified Zeiss fundus camera. Chapter 10 provides a complete monograph on the anatomy, physiology, and clinical aspects of the seventh cranial nerve and the articularis oculi by W. F. Hoyt, M.D. The reader appreciates that eyelid tics are not always benign. N. J. David, M.D., reviews the syndromes of the basilar artery and emphasizes the importance of Horner's syndrome in softenings of the lateral medullary plate. The volume concludes with a well illustrated discussion of the so-called phakomatoses, including Bohrneville's, Von Recklinghausen's, Sturge-Weber and Von Hippel-Lindau syndromes.

William S. McClanahan, M.D.
Minneapolis, Minnesota

APPLIED VIROLOGY — **Murray Sanders and Edwin Lennette (Editors), Olympic Press, Sheboygan, Wisc., 1965, $7.50, 319 pages.**

This paperback volume contains the proceedings of the First Annual Symposium on Applied Virology. Seventeen papers, given by 30 virologists from four countries, cover subjects ranging from diagnostic techniques to viral zoonoses to oncogenesis by viruses. The editors trim the talks and discussions to readable form and retain some excellent illustrative material. Included are such practical and current topics as collection of specimens, interpretation of results, use of flourescent-antibody techniques, role of *Mycoplasma* organisms in human disease, experiences with live vaccines in upper respiratory infections, and advent of antiviral agents. The book will be rewarding for physicians interested in viral disease.

Richard L. Reece, M.D.
Minneapolis, Minnesota

COMMUNICABLE AND INFECTIOUS DISEASES — **Franklin H. Top, 5th edition 1964. C. V. Mosby Company, 920 pages.**

This is the 5th edition of an established reference monograph on communicable and infectious diseases; twenty-five outstanding authorities on infectious diseases have contributed to this edition. The book is primarily intended for the clinician. The first section is devoted to general consideration of epidemiology, regulation and control of communicable diseases, chemotherapeutic and antibiotic agents and their reaction. Included in this general section are two excellent chapters on the management of communicable diseases in the hospital and the home. The remainder of the book is devoted to a discussion of primarily the clinical considerations in diagnosis, course and treatment of viral, fungus and infectious diseases, which are classified according to their portal of entry into the body and the main organs involved with the infectious agent. This creates some problems in using the book as a quick reference for specific infectious diseases; however, it has the advantage of discussing the various diseases in relation to their primary clinical manifestation.

The text is very well illustrated with both black and white and color illustrations and has quite complete references at the end of each section. I found the book to be comprehensive and detailed in its discussion, yet relatively easy to read and use as a reference text. This book will be a very useful and interesting one to all physicians encountering communicable and infectious diseases in their patients.

Gleanings from the Meetings

Annual Meeting
Society of Thoracic Surgeons
Denver, Colo. Jan. 24-26, 1966

Mediastinotomy

Diagnostic anterior mediastinotomy is a relatively simple procedure as described by Drs. McNeill and Chamberlain.* The procedure is diagnostic, employed only in patients with thoracic disease beyond surgical intervention.

The procedure is an extrapleural approach via the bed of the second costal cartilage. If desired, the pleura can be opened and a lung biopsy obtained. General anesthesia is employed. Scalene node removal is done first.

This approach has the advantage of a more thorough exploration of the mediastinum than can be obtained by midline mediastinoscopy. The disability is no greater and the yield of positive results higher. Likewise, control of bleeding, etc. would seem easier.

Mediastinitis

Progressing fibrosing mediastinitis and histoplasmosis may have a direct relationship. Drs. Hewlett, Steer, and Thomas** presented evidence of this relationship in 14 patients, 12 of whom had the progressive debilitating form of disease.

Not all patients with enlarged mediastinal nodes of histoplasmosis infection will develop the progressive pseudotumor invasion of the mediastinum. However, if the disease does "break out" of node encapsulation, no known medical or surgical treatment will prevent progressive venacaval obstruction, bronchial stenosis, and death from invasion by the sclerosing process.

The authors suggest early surgical removal of noninvasive enlarged lymph nodes secondary to histoplasmosis. The photographs of autopsy specimens of the final stages support this attitude.

Editors note: Minnesota is an endemic area of histoplasmosis. Physicians should be alert to this disease and perform skin tests and serum agglutinin titers on all patients with mediastinal node enlargement.

Permanent Pacemaker Insertion — An Appraisal
— V. Parsonnet, M.D., L. Gilbert, M.D., I. R. Zucker, M.D.

The authors related their experience with 87 patients who had an electrical pacemaker for atrioventricular block. One hundred and three pacemaker units were placed by either intravenous, transthoracic, or transdiaphragmatic route. There was one operative death. Thirty patients required more than one operation before a satisfactory function pacemaker unit was achieved; failures were related to the apparatus and technique of placement.

The safest technique for bad-risk patients is the transvenous via the left cephalic vein, permanently implanting the battery in the subpectoral area

---

*"Diagnostic Anterior Mediastinotomy." T. M. McNeill, M.D., J. M. Chamberlain, M.D.

*"Progressive Fibrosing Mediastinitis." T. H. Lewlett, M.D., A. Steer, M.D., D. E. Thomas, M.D.

Continued

under local anesthesia. Two years' experience suggests this may be the route of choice. No anticoagulants are needed.

One discussant (J. H. Kennedy) suggested performing cardiac output determinations before and after pacing with the transvenous electrode. If the cardiac output falls with electrical pacing, primary myocardial insufficiency contraindicates further pacing.

The other techniques of operative insertion were described. However, the transvenous approach seems most logical if the reported low morbidity remains valid with further passage of time.

Evaluation of a Technique to Prevent Aortic Regurgitation Using the Magovern Prosthesis — N. Zuhdi, M.D., J. Carey, M.D., A. Greer, M.D.

An interesting solution was presented to offset the problem of postoperative regurgitation about the Magovern sutureless aortic valve prosthesis. This prosthesis has the advantage of quick, easy multiprong fixation after removal of a diseased aortic valve. However, despite modifications of the prosthesis, most surgeons find a major number of patients with audible aortic regurgitation — i.e., the valve rim does not effectively seal against the aortic wall. The degree of regurgitation may become hemodynamically significant and therefore a serious postoperative complication. Various techniques to prevent this have been devised.

Dr. Zuhdi has approached this problem utilizing principles of resultant forces in/during the thrust of volume expansion of a tube (the aorta) with a fixed point (the aortic valve annulus). The resultant lateral vector force is at this point — the apex of the angle of aortic expansion — and the site of regurgitation; therefore Dr. Zuhdi minimizes this lateral vector by preventing aortic expansion and narrowing the angle thereof. He wraps the ascending aorta with a one-inch teflon cloth and thereby prevents regurgitation.

An interesting application of mechanics.

Gulliver's Travels — Jonathan Swift*

Gulliver — On Crooked Politicians

"The Palace of a chief minister is a seminary to breed up others in his own trade: the pages, lackeys and porters by imitating their master, become ministers of state in their several districts and learn to excel in the three principal ingredients of isolence, lying, and bribery. Accordingly, they have a subaltern court paid to them by persons of the best rank; and sometimes by the force of dexterity and impudence, arrive through several gradations to be successors of their lord.

He is usually governed by a decayed wench, or favored footman, who are the tunnels through which all graces are conveyed, and may properly be called, in the last resort, the governors of the kingdom.

By 'an act of indemnity' they secure themselves from after-reckonings, and retire from the public, laden with the spoils of the nation."

". . . and the serum sodium is 134 mEq/L."

THE CLINICIAN is called upon daily to assess measurement values ranging from serum sodium concentrations to blood pressure readings. Decisions about the meaning of such measurements are based on his evaluation of multiple variables including a comparison with the results that might be expected if the patient were *not ill.* In other words, each step of the diagnostic process calls for a comparison between the patient's values and *Normal Values.*

In the hypothetical report cited above one must decide whether this value is normal, i.e., within the range of physiologic variation, or whether it is abnormal. Will the patient need further investigation or specific therapy? Obviously, the physician would want to gather more information about his patient before arriving at a conclusion. One thing he would want to know would be the normal value of serum sodium. He would consult the pathologist concerning his laboratory's experience, and since the individual laboratory generally establishes normal value limits on a small number of subjects, the clinician and the pathologist must together consider the values reported in the standard textbooks, as shown in Table 1.

If uncertain after consulting the textbooks and finding no indication of the populations on which the information was based, they might consult original articles dealing, for example, with normal values of serum or plasma sodium as measured by flame photometry, as shown in Table 2. If the patient did not happen to be a "normal adult," the issue would depend on clinical information and other laboratory data. The doctor's dilemma serves as an example of the unquestioned importance of meaningful standards for evaluation of laboratory data.

Just how *normal* are normal values?

This discussion will be limited to the general field of laboratory medicine, although the principles apply equally well to the parent discipline of biometry. The inclusion of this article in a special edition dedicated to Dr. Gerald T. Evans is appropriate for several reasons. Most important is the fact that normal values must be based on good measuring devices, e.g., a reliable laboratory. It is for this that Dr. Evans has devoted 25 years of service to the University of Minne-

sota. He has always emphasized the importance and difficulty of establishing good, normal values based on the highest quality of practical measurement. The growth of laboratory medicine reflects the burgeoning knowledge in the basic sciences. These are being translated into clinical applications by the combined efforts of well-informed clinicians and the efforts of men like Dr. Evans who have chosen to build a bridge between the basic and applied sciences. One of the recognized foundations of such a bridge is the concept of normal values, the subject of this article.

Semantics

Terminology is a problem that needs consideration. Albritton[9] and others have used the term "standard"* values, but the term "normal"** is the more commonly used and according to its definition,[10] it is more appropriate. Sunderman[11] refers to the "norm" as a selected range of values obtained from apparently healthy people whose individual values would then be classed as "normal." Consideration has even been given to establishing "ideal" values rather than the "normal" values based on averages, but too little information exists on what is really "ideal." In this paper the term "normal values" will be used.

Variability

Table 3 lists some of the factors which affect medical laboratory measurement. Because of increased use of quality control techniques the clinician expects to know from the laboratory what the "confidence limits" are for a particular test. For example, with serum sodium he might expect the value reported as 134 mEq/L to actually lie somewhere between 131 and 137 mEq/L in 95% of replicate determinations of the same specimen.[12]

Different methods and laboratory variation also affect tables of normal values. The measurement of sodium by flame photometry is a reliable method; yet methodology[13] may be one of the factors contributing to the apparent inconsistencies appearing in Tables 1 and 2. Methodology in other tests, e.g., red blood count and uric acid, plays a more important role in affecting differences between results from various laboratories.

TABLE I
Normal Values of Serum as Recorded in Various Textbooks

Range meq/L	Senior Author or Editor	Title	Year
130-143	Gradwohl, R. B. H.	Clinical laboratory diagnosis	1963
130-143	Levinson, S. A.	Clinical laboratory diagnosis	1961
132-142	Harrison, T. R.	Principles of internal medicine	1962
133-143	Eastham, R. D.	Biochemical values in clinical medicine	1960
133-148	Davidsohn, I.	Todd & Sanford's clinical diagnosis by laboratory methods	1962
136-145	Beeson, P. B.	Cecil-Loeb's textbook of medicine	1963

---

*The pertinent sections read: *Standard:* ". . . 3. Something that is established by authority, custom or general consent as a model or example to be followed. 4. Something that is set up and established by authority as a rule for the measure of quantity, weight, extent, value or quality."

***Normal:* ". . . 3.b. Occurring naturally and not because of diseases, inoculation or any experimental therapy. 4.c. Characterized by balanced and well integrated functioning of the organism as a whole within the limits imposed by the environment and in accord with the pattern of one's biological endowment. 6. Approximately the statistical norm or average.

In attempting to arrive at limits which apply to a population, both method variations and variations in the same person contribute to the range and, additionally, there is the unique factor of the difference *between* individuals. This last item can be illustrated by using the height of an adult. The height of a single individual would vary only slightly if measured day to day. The range of normal values for height in a population leads to a wide range of *inter-individual* variability due to factors cited in Table 3. Inter-individual variations are assumed not to be as great for most laboratory tests.

The example of serum sodium not only illustrates the inconsistency of reported normal values, but makes obvious the problems of the borderline value. Had the value been reported as either 127 or 140 mEq/L, the implications would be much clearer. But the area where the normal population values overlap the abnormal ones is where

TABLE 3
Variables in Medical Laboratory Measurements

Patient Factors
- Condition
  - Physiologic: e.g., fasting, post exercise, pregnant.
  - Pathologic: This is generally the variable which is under consideration for determination.
- Age
- Sex
- Environmental: e.g., altitude, urban or rural, climate, socioeconomic.
- Genetic: Race, familial disposition.
- Time of specimen collection: Period of collection, diurnal variation, cyclic phenomenon.

Methodology
- Collection technique
- Preservation of specimen
- Measurement technique: Precision and accuracy.

TABLE 2
Normal Values of Serum (or Plasma) Sodium Measured by Flame Photometry as Recorded in Original Investigations

Range meq/L	Average	Standard Deviation	Year	Number of Subjects	Senior Author and Comment*
132-144	--	--	1963	157	Flear, G. T. G.:[1] 85 females and 72 males between the ages of 16 and 55. Hospital employees.
133-152	--	--	1953	50-100	Wooton, I. D. P.:[2] Aged 18-50; fasted four hours; no known systemic disease.

*In general, the commentary includes *all* of the information described in the original articles with regard to the age and sex distribution and the health status of the sample.

Continued

the physician needs the greatest help from meaningful measurements in healthy people with as many of the same variable factors as in his own patient. Unfortunately, the dilemma posed by Tables 1 and 2 is often worse for other parameters which do not share the relatively narrow range of serum sodium or the relative precision of measurement of this element by flame photometry. There is need in normal value tables for a definition of the characteristics of the population from which the "yardsticks" are derived.

Normal Value Data Sources

In 1949 Sunderman and Boerner,[11] in a remarkable publication, compiled tables with specific reference to studies of normal values. Unfortunately, their activity seems to have aroused little interest or enthusiasm. We still know little about the "normal" range of the "normal" population.

Small Healthy Group

The "ten-handiest-people" approach is well established and convenient but has little else to recommend it. Usually there is a marked bias in age and sex selection, making any extrapolations unreliable. Generally the health of subjects is assumed rather than proved, but the smallness of the group makes control of the health factors easier than with larger groups.

Larger Selected Groups

In these studies, medical students and student nurses are often used; but also armed forces, inmates of penal institutions, blood bank donors, well-baby clinics, and other special aggregations are employed for determinations. Such groups are large and in good health and can provide fairly good data. The age-sex selection bias in such groups may be an advantage in applying the values to similar individuals, or, in statistical terms, the cohort group. The extrapolation of data to more heterogeneous populations should be done only after making sure that the original group is a valid sample of the larger population.

Routine Laboratory Data

Recently Hoffman[14] has emphasized the potential of utilizing routine hospital or office laboratory data to determine normal values. This proposal is of particular interest because, if its reliability were to be established, the values obtained would be much more closely based on the local situation than the usual standard tables. However, this technique demands certain important assumptions which need to be tested in practice. The system is based on the premise that a great majority of specimens routinely analyzed in the laboratory show results which fall close to the previously suggested normal values. Hoffman has manipulated this data by statistical means and with some arbitrary exclusions has divided these into normal and abnormal groups and has used the former as the basis for the normal values for a particular laboratory.

Epidemiologic Approach

In contrast to the sample bias inherent in the previous categories, an effort to select random samples from the healthy population at large would most nearly ascertain the *truly* normal value range of any given characteristic. Such an undertaking is expensive, time-consuming, and difficult to achieve. It has been done in surveys of limited population groups and in a modified form recently for a single community,[15] but it includes in its shortcomings the problem of the definition of normality. The possibility that a representation of abnormals might be included by design would actually help to clarify the critical area of overlap between high (or low) normal subject values and low (or high) abnormal subject values. However, that would entail even greater work in defining the health status of the population studied.

Individual Normal Values

Previously, in defining normal values, it has been assumed that because of the inherent variation between individuals, the determined range for a group in respect to any one variable would exceed the range of any normal individual responding to the usual physiologic stresses. Accordingly, it can be postulated that in some instances an individual may become ill and several of his values change significantly from his normal range and yet still lie within the broader range of the group normal values. Schneider[16] discusses and illustrates this point as regards transaminase determinations.

In essence, this is an extension of the principle already applied in establishing a "base line" EKG or an initial chest x-ray. It is hoped that eventually it will be possible to determine by periodic reexamination a range of values that will meaningfully define each patient's individual variation in health.

If such a program were to be widely adopted, it would require a great increase in the volume of prophylactic or data-gathering determinations from asymptomatic patients. Increased emphasis on laboratory stability (defined variability over long periods of time) and interchangeability of data from laboratory to laboratory would be desirable. It would still be necessary, however, to have inter-individual data values, but these could be obtained from information available in multiple individual patients' profiles.

In general, data obtained from any special group has limitations in its applicability. These limitations are best understood when the group is well defined and its relationship to the individual patient is clear. This principle emphasizes the importance of categorization of normals where meaningful differences can be established. For example, although there is evidence to the contrary[17] it is generally assumed that the value of serum sodium is not affected by age or sex, but hemoglobin concentration definitely is, as are many other substances or functions. Because of the lack of specific information on normal distributions with regard to the many known and unknown variable factors, some hospitals specially designate only those values lying outside the upper and lower 2½% of all determinations in that hospital. This serves to alert the physician to his patient's differences from a specific population but does not identify the result in terms of normal or abnormal. In view of the indefinite status of "normality," this approach has certain merit as well as weaknesses.

Statistical Analysis

Statistics are important in the analysis and application of the data obtained. It is a statistical aphorism that no analysis is better than the data with which it deals. If the normal values are biased by sample selection, there is no statistical way to extrapolate meaningfully beyond the real population. Selected populations can be randomly or completely sampled, though, and the statistical manipulation of the data can make them more meaningful and more useful when applied to the base population or compared to a different one.

Normal Distribution

The concepts of the normal curve, the mean and the standard deviations are generally familiar to medical practitioners. Because there is an overlap in values between normals and abnormals, as previously discussed, the determination of abnormality cannot be based on a borderline level. As a matter of clinical judgement, the physician weighs the laboratory data with his own and other findings and either establishes or rejects a given diagnosis. He judges the value in terms of the probability that it might occur normally and, accordingly, he should be able to describe accurately the percentage of normal people who might be expected to yield such a value or a higher or lower one. A normal distribution curve that can be applied in this manner is the goal of many normal value studies. Since theoretically 95% of the larger population from which the group is drawn will fall within a range of ± 2 standard deviations, these are generally accepted as the working limits of the normal range. The benefits of this reasoning are well known and some of the pitfalls of poorly defined normal values have been indicated. What has not been mentioned is that *not all* laboratory values follow normal curve distributions and that in these instances other rules apply.

Log Normal Distribution

Henry[18] has emphasized that many biological phenomena vary according to an exponential function rather than arithmeti-

Continued

cally. Population values distributed in this manner show a skewed arithmetic curve, and applying normal distribution statistics to these data (unless they are transformed to the logarithmic function) leads to unreasonable and unmeaningful results. "Normal values" analyzed improperly are not only meaningless but can be grossly misleading.

Multivariate Analysis

The laboratory diagnostic aids usually concern only one or two variables in terms of their interrelationships. Lindberg[19] has demonstrated an approach to the analysis of routine laboratory data with electrolytes that consider the simultaneous variation of four separate parameters, and biostatisticians have the tools to analyze simultaneously even more variables.

In the brave new computerized world it may be possible to characterize a previously occult disease syndrome by its laboratory profile in "ten-dimensional space." The most highly developed computer, man's own brain, deals with multiple variants in the diagnostic process. When automated laboratory facilities can be coupled with electronic data processing, the diagnostician's insight should be extended to new horizons with clearly defined, unambiguous ranges of normal values by which to judge his individual patient.

Summary

Normal values are fundamental to the practice of medicine. A clear definition of the basis on which they are gathered and the mathematical extrapolations and limitations to which they are subjected are necessary for best utilization. The increasing accuracy and precision of the individual laboratory measurement will become more meaningful when a corresponding degree of care is taken to formulate the scale against which values must be compared. Activity and progress in this field are increasing. Elsewhere it has been suggested that each community can be active in accumulating its own normal value data. Well-practiced laboratory medicine, intelligent statistical analysis and electronic computational tools are leading to new concepts and applications in this area.

Medical Technology Education*

RUTH F. HOVDE**
Minneapolis, Minnesota

IN THE LAST 42 years there have been 1,338 graduates of the University of Minnesota with Medical Technology degrees. The curriculum was originally under the jurisdiction of a committee of the Medical School composed of Dr. S. Marx White, Dr. Wilfred Larsen, and Dr. Richard Beard. The four-year degree program, the first of its kind in the United States, was, at that time, a daring innovation. In 1925 Dr. William O'Brien took over the chairmanship of the committee. Under his leadership the curriculum content and clinical training expanded and became more clearly defined.

In 1940 Dr. Evans assumed responsibility for directing the program. Through his abilities, creativity, imagination, and understanding of people the school became nationally recognized as a leader in the education of medical technologists. He repudiated the apprenticeship system which was dominated by the service demands of the hospital. He demanded quality in the courses given and in the faculty that taught them. He led the struggle for the national minimum requirement of four years of education at the college level for certification as a medical technologist. Today universities and hospital schools throughout the country use the curriculum and practices set forth by Dr. Evans.

He foresaw that the growth and utilization of the clinical laboratory would result in a shortage of technologists. To forestall this he helped set up the first program for medical laboratory assistants. To date 378 students have completed the course. Of these, 76% are still in the working force, primarily in hospital laboratories and physicians' offices. There are now 77 schools approved for training medical laboratory assistants in

the United States, their curriculums largely guided by the experiences and programs established here.

In order that Medical Technology flourish, Dr. Evans recognized the need for continuation of education beyond the B.S. degree. In 1960 he helped establish a graduate program in medical technology leading to a Master of Science degree and providing the opportunity for technologists of superior ability to continue academic work under the auspices of the Graduate School. To date, four students have completed the Master's program. All four are in educational programs in schools of Medical Technology.

As a young profession Medical Technology is faced with difficult problems in education brought about by increasing complexities and demands in the clinical laboratory. Historically, laboratory personnel were trained on the job as assistants or as apprentices in private hospitals, with no standardized curricula or basic academic preparation. The purpose of the training programs, if they could be called that, was to ensure a supply of future workers. The students were taught only "know-how," in the belief that methods would not change during their working lifetime. But methods did change, and the laboratories found their technicians could not adjust.

A national concern by medical educators developed over the poor quality of Medical Technology education. The hospitals turned to the colleges and universities for academic affiliation, and it became apparent that a standardized curriculum was needed.

As medical educators in the Universities and Medical Centers we must recognize our responsibilities in educating medical technologists. Should the onus for education rest on the medical schools, or will hospital laboratories continue to play the dominant role? The hospital's task is primarily to provide care for the sick. Training medical technologists is a job for which hospitals never were intended. Their educational programs — the product of the apprentice system — often are not systematic or broad. Cognizance must be given to an organized, rounded, and academic approach in teaching.

Hospital schools are forced to limit their techniques to those demanded by the service needs of the hospital. They cannot, in the twelve-month period allotted to their programs, cover the spectrum of techniques and instruments used in the modern clinical laboratory. One survey reported that the technologist in a modern hospital laboratory performs as many as 871 functions, falling into 19 categories. In these circumstances it is impossible to learn both theory and techniques.

How can a balance between knowledge and application of basic sciences be achieved in a college curriculum? Will learning practical technique be included in the training? The function of higher education is to provide the ability to understand theory so that practical skills can be attained later. The programs must include a broad approach to science with emphasis on the creative application. The technologist must have responsibility for the application of knowledge in the laboratory; he must have creativity, ability, and flexibility. To produce these persons the program of education must be reappraised.

Will extension to a five-year program be the answer in Medical Technology? It could be. But what about money for students in such a course? At the present time, salaries for the graduate medical technologist will not lure many students into a five-year course. Medical Technology attracts mostly young women, and women are not inclined to spend five years in a collegiate program.

But demands for laboratory services are increasing, and the problems of the medical technologist's education must be resolved. Among these problems are: (1) Automation — Automation is rapidly approaching, but small hospitals do not yet have the volume to warrant investment in automated equipment. Therefore, we must give students experiences with both hand methods and automated methods. (2) Specialization — With complexity comes fragmentation into special fields. Should the university produce specialists or generalists? Small hospitals cannot support a staff of specialists, and the generalist will continue to be dominant — especially during the night shifts. (3) The gifted students — How can the talents of the gifted student be used? Presently, requirements and standards are geared to the average. Bright students should be encouraged to go to graduate school and to enter into teaching or research in Medical Technology. (4) Continuing education — To keep up with advances in technology, especially in instrumentation, refresher courses must be given.

I hope I have brought into focus some of the problems of medical technology education. These would have been much greater if it had not been for the accomplishments and vision of Dr. Evans.

In anxiety states: B and C vitamins are therapy

Stress formula vitamins are an important supportive measure in maintaining the nutritional status of the emotionally disturbed patient. With STRESSCAPS, B and C vitamins are present in therapeutic amounts to meet increased metabolic demands. Patients with anxiety, and many others undergoing physiologic stress, may benefit from vitamin therapy with STRESSCAPS.

Each capsule contains:

Vitamin B_1 (as Thiamine Mononitrate)	10 mg.
Vitamin B_2 (Riboflavin)	10 mg.
Niacinamide	100 mg.
Vitamin C (Ascorbic Acid)	300 mg.
Vitamin B_6 (Pyridoxine HCl)	2 mg.
Vitamin B_{12} Crystalline	4 mcgm.
Calcium Pantothenate	20 mg.

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

STRESSCAPS®

FOR PROFESSIONAL RECOMMENDATION ONLY

History of Medicine

The Discovery of Insulin

Part II

I think it is pertinent to the story of the discovery of insulin to clarify at this time what there was in the article in the issue of "Surgery, Gynecology and Obstetrics" of November 1920 that so sparked the imagination of Dr. Banting that he could not sleep that night, as he tells it, for pondering on the new ideas suggested to him by this article. He found here a wholly new approach: how one might obtain the hormone which appeared to control carbohydrate metabolism, freed from the contaminating digestive ferments which ordinarily are present in the pancreatic extract, when the pancreatic duct has not previously been ligated.

This problem of how to cope with the presence of the protein-digesting ferments in the extracts of the pancreas, which destroy the antidiabetic hormone of the Islets, since it is a protein and therefore subject to digestion, had previously frustrated researchers for more than 25 years before Banting's time.

The article which Dr. Banting referred to described a case which I had observed at postmortem, in which the pancreas was most unusual. Though the length was normal, its thickness was reduced to about one third of the normal measurement, and instead of being solid, on cross-section it was found to be hollow, containing fluid and giving the appearance of rubber tubing. At the lower end it was filled with pancreatic stones, completely obstructing the duct. Microscopic sections showed the wall to be composed of scattered Islets of Langerhans imbedded in scar tissue with some inflammatory cells. There were no acinar cells present, which produce the digestive ferments. The striking feature of this microscopic picture was the complete absence of those cells which secrete the digestive juices; whereas the Islet cells were practically intact. Clinically there was no evidence of diabetes.

This condition impressed me as being so unusual that I reviewed the literature on the subject and became especially interested in the histopathology that had been found in experimental ligation of the pancreatic ducts in animals.

I noted in the literature that surgical ligations of the pancreatic ducts in animals produced findings almost identical with those I had noted in this autopsy. An example of this is to be found in the experiments of Sobolew, who in 1902 ligated the pancreatic ducts in rabbits, cats, and dogs, and found that following the ligation of the ducts there was atrophy and sclerosis of the pancreas, unaccompanied by glycosuria. Microscopically, the Islets remained practically intact. Similar results from ligating the ducts had been obtained by Kamimura. In 1917 when he ligated the ducts in 100 rabbits, he found that at the end of the second week the normal structure of the cells had been so altered that they were scarcely identifiable as pancreatic tissue, and that, during the fifth week, very few nests of parenchymal cells were visible. The entire organ had been replaced by scar tissue, but the Islet cells were still intact. However, the examination of the blood and urine had shown neither hyperglycemia nor glycosuria.

From this Kamimura concluded that the Islets controlled carbohydrate

Continued

metabolism through the production of some internal secretion, and that destruction of the glandular portion of the organ through ligation was in no way connected with the utilization of sugar. It was the description of these experiments and of others of similar character, together with the description of that very rare and unique condition of the pancreas found at the postmortem I had performed, that led Banting to realize the possibility of obtaining by ligation an antidiabetic hormone from the pancreas, free from admixture of the enzymatic secretion which is bound to destroy the antidiabetic hormone by digestion and also to prove toxic on injection.

It was the revelation of this fact which immediately excited Dr. Banting to conceive the idea of the possibility of attacking the problem of how to obtain a pure secretion of the Islet cells for the treatment of diabetes. To quote Dr. Banting's words, "It was not until 2 o'clock in the morning that I was able to crystallize the idea into a form that would lend itself to experimentation."

This is the story of the discovery of insulin by Dr. Banting.

It is impossible to estimate the far-reaching results of this great boon to mankind, the lives it has saved, the suffering it has spared. Today there are in this country alone two and a half to three million diabetics, for more than half of whom life has been prolonged and living made more comfortable through the use of insulin.

In his short life of fifty years (1891-1941) Dr. Banting was able to do so much for mankind.

I would like to pay my personal tribute to Doctor Banting as a man, for I believe he showed greatness in the way he unstintingly, in his writings and in his lectures, acknowledged the fact that his discovery followed the reading of my article. Such forthrightness is not to be taken for granted.

Moses Barron, M.D.*
Minneapolis, Minnesota

The Delight of Victory

There takes place between a disease and a doctor . . . such a struggle as doctors alone know. The reward for it, should it be successful, is never the venal fee, nor even anything that happens to the patient. It consists in a pleasant satisfaction of mind and in some sort of ideal and invisible laurel, such as is gained by any true artist who is certain that he has done a good work. The physician strives for the good as the artist strives for the beautiful, each pushed on by that admirable feeling we call virtue.

— Honore de Balzac (1799-1850)

113th Annual Meeting

Call to Order

Annual Meeting Events Highlighted

W-e-l-c-o-m-e to St. Paul! Your host members of the Ramsey County Medical Society welcome all Minnesota physicians and their wives to attend the 113th Annual Meeting of the Minnesota State Medical Association, May 16 and 17 in St. Paul.

The 1966 scientific sessions will be held at the St. Paul Municipal Auditorium. The House of Delegates will convene Sunday, May 15 at 2:00 P.M. at the St. Paul Hotel.

American Medical Association President, Dr. James Z. Appel, will address delegates at their opening session on Sunday, May 15. He will also be the speaker at the new members, county officers, and delegates dinner on Sunday evening. The House will reconvene Tuesday, May 17 at 9:00 A.M.

Pre-registration for attendance at this year's meeting has been recommended by the Committee on Scientific Assembly. Registration materials have been included with earlier mailings of the Executive Secretary's Newspage for your convenience. By preregistering before May 10, physicians will be assured that their badges will be waiting for them at the advance registration desk at the St. Paul Auditorium.

Physicians are also urged to use the card enclosed with advance registration materials to make room reservations early.

Register or secure your badge at the registration desk in the St. Paul Municipal Auditorium on Monday, May 16 from 8:45 A.M. to 5:15 P.M., and Tuesday from 8:45 A.M. to 5:15 P.M.

Advance registration for the Round Table Luncheons Monday and Tuesday noon is desirable. Tickets should preferably be purchased in advance by completing and returning the advance registration cards enclosed with the official annual meeting program mailed to all members. Round Table Luncheon tickets may also be purchased at the St. Paul Auditorium registration desk. As in the past, latecomers will be accomodated according to their choice if luncheon limits have not already been reached.

The annual banquet on Tuesday, May 17 will be preceded by a social hour at 6:00 P.M. Banquet activities will feature outstanding entertainment, including a floor show and dancing.

Fifty club members will be honored guests and a medal for the outstanding scientific exhibit will be presented by the Southern Minnesota Medical Association.

For golfers there will be the annual tournament on Sunday, May 15 at the White Bear Yacht Club. The tournament will be followed by a 6:15 P.M. golfers dinner to which all members of the Association and their wives are cordially invited.

The Minnesota State Medical Association Fourth Duplicate Bridge Tournament is scheduled to begin Monday at 9:00 P.M. at the St. Paul Hotel. The tournament is open to all bridge players and duplicate experience is not necessary.

Among the many excellent features on this year's Scientific Assembly Program will be a discussion on the "Prevention and Treatment of Knee Injuries in the Athlete." This discussion is scheduled for 11:00 on Tuesday, May 17, and will include a paper by Dr. Harvey O'Phelan, Minneapolis. Professor Lloyd Stein of the University of Minnesota Athletic Department will demonstrate the

Continued

taping of injuries.

The Minnesota Society of Clinical Pathologists will hold a one day session in conjunction with the annual meeting, beginning at 9:00 A.M., Monday, May 16, in the Minnesota Club.

The Minnesota Academy of General Practice will hold its annual banquet on Monday evening.

Other organizations and specialty groups which have scheduled events in conjunction with the meeting include the Minnesota Radiological Society, Twin Cities Diabetes Association, Minnesota Chapter, American College of Chest Physicians, Minnesota Chapter of American Academy of Pediatrics, Minnesota Academy of Ophthalmology and Otolaryngology and The Medical Women's Association.

To help physicians become better acquainted with the provisions of PL 89-97, the Minnesota State Medical Association will present a special program on Medicare Wednesday, May 18, at 9:00 A.M. in the St. Paul Hotel, the day immediately following the close of our Annual Meeting. The program will feature representatives of HEW, AMA, the Minnesota Department of Public Welfare, who will explain and answer questions about the operation of Medicare. Because the program has been particularly arranged to meet the needs of the physician in his daily practice, all physicians are urged to make plans now to attend our Annual Meeting, including this important seminar.

Committee breakfasts have been scheduled by many of the scientific and non-scientific committees. Members are urged to attend and participate in the activities of their respective committees also.

Scientific Program

Saint Paul Auditorium

MONDAY MORNING, MAY 16, 1966

The program on Monday is acceptable for 4½ accredited hours by the American Academy of General Practice.

A.M. Visit scientific and technical exhibits

9:00 **COMPUTER MEDICINE: ITS APPLICATION TODAY AND TOMORROW**
Morris F. Collen, Oakland, California

9:40 **WHAT'S NEW IN HEMATOLOGY?**
A. B. Hagedorn, Rochester

10:15 Visit scientific and technical exhibits

11:00 **OBSTRUCTIVE RESPIRATORY DISEASES**
William R. Fifer, Minneapolis
Moderator
Norman G. Hepper, Rochester
James P. Lillehei, Minneapolis
Frank M. MacDonald, Minneapolis

MONDAY AFTERNOON

P.M.

12:15 **ROUND TABLE LUNCHEONS**

1:30 Visit scientific and technical exhibits

2:00 **TREATMENT OF BURNS**
Carl A. Moyer, Houghton, Michigan

2:30 **PANEL ON THE DYING AND THE DEAD**
Harold W. Hermann, Minneapolis
Moderator
Bishop James P. Shannon, St. Paul
Chairman
Rev. Elmer Hjortland, Oak Park, Illinois
Rabbi Albert G. Minda, Minneapolis

3:30 Visit scientific and technical exhibits

4:00 **RESPIRATORY DISTRESS SYNDROME IN THE NEWBORN**
Mary Ellen Avery, Baltimore, Maryland
Martha B. Strickland, St. Paul
Discussant

TUESDAY MORNING, MAY 17, 1966

The program on Tuesday is acceptable for 4½ accredited hours by the American Academy of General Practice.

A.M. Visit scientific and technical exhibits

9:00 **ISOTOPES AS A DIAGNOSTIC TOOL**
Paul V. Harper, Chicago, Illinois

9:40 **DIAGNOSIS AND TREATMENT OF HYPERTHYROIDISM**
L. O. Underdahl, Rochester

10:15 Visit scientific and technical exhibits

11:00 **PREVENTION AND TREATMENT OF KNEE INJURIES IN THE ATHLETE**
Harvey O'Phelan, Minneapolis
Professor Lloyd Stein, University of Minnesota

TUESDAY AFTERNOON

P.M.

12:15 **ROUND TABLE LUNCHEONS**

1:30 Visit scientific and technical exhibits

2:00 **JUVENILE DIABETES**
Priscilla White, Boston, Massachusetts
Donnell D. Etzwiler, Minneapolis
Discussant

TUESDAY AFTERNOON CONTINUED

2:30 **MANAGEMENT OF STREPTOCOCCAL AND STAPHYLOCOCCAL INFECTIONS: NEWER CONCEPTS**
Donald R. Nichols, Rochester

3:00 Visit scientific and technical exhibits

3:30 **THE EARLY RECOGNITION AND PREVENTION OF BLINDNESS**
Robert Hugh Monahan, St. Paul

4:00 **THE OB-GYN SEMINAR**
"Endometriosis, the Conservative vs. the Radical Surgical Treatment"
Bruce F. P. Williams, Duluth
"*Early* Invasive Carcinoma of the Cervix"
John M. McKelvey, Minneapolis
Joseph H. Pratt, Jr., Rochester

TUESDAY EVENING

7:00 **ANNUAL BANQUET**
Reception
Presentations
Entertainment, Dancing and Late Evening Buffet

Round Table Luncheons

Saint Paul Hotel

MONDAY — 12:15 P.M.

Fluids in Infancy
Mary Ellen Avery, Baltimore, Maryland

The Spiritual Dimension of Suffering
Harold W. Hermann, Minneapolis
W. F. Widen, Minneapolis

The Use of Saline Solutions in the Treatment of Hemorrhagic and Traumatic Shock
Carl A. Moyer, Houghton, Michigan

Treatment of Leukemia
A. B. Hagedorn, Rochester

Management of Emphysema
William R. Fifer, Minneapolis

Computers in Preventive Medical Research
Morris F. Collen, Oakland, California

TUESDAY — 12:15 P.M.

Prevention and Treatment of Ankle Injuries
Professor Lloyd Stein, Minneapolis

Value and Use of the Tonometer
Robert Hugh Monahan, St. Paul

The Brittle Diabetic
Priscilla White, Boston, Massachusetts

Radioactive Isotopes in Clinical Practice
Paul V. Harper, Chicago, Illinois

Amniocentesis, A Diagnostic and Therapeutic Tool
Bruce F. P. Williams, Duluth

Therapeutic Abortion in General and in Rubella
John M. McKelvey, Minneapolis

Program Highlights

. . . Dr. James Z. Appel, President of the American Medical Association, will address the House of Delegates at their opening session on Sunday, May 15. He will also be the speaker at the New Members, County Officers and Delegates dinner on Sunday evening.

. . . Please reserve Wednesday, May 18, following the annual meeting for a seminar on Medicare at the Saint Paul Hotel, beginning at 9:00 a.m. Representatives of HEW, AMA, the Travelers Insurance Company, the Minnesota Welfare Department, and other officials will discuss the many facets of Medicare, including Title XIX.

. . . For golfers — The annual golf tournament will be held on Sunday, May 15, at the White Bear Yacht Club followed by a dinner at 6:15 p.m. to which all members of the Association and their wives are cordially invited.

. . . Special attention is called to the day-long session on Monday of the Minnesota Society of Clinical Pathologists which begins at 9:00 a.m. at the Minnesota Club and continues through 4:30 p.m. The program will include a symposium on "Evaluation of Thyroid Function," and beginning at 2:00 p.m. "Case Reports" with panelists.

. . . Advance registration card for the meeting and the card for hotel accommodations were sent to all members with the Association's March newsletter. Use of these cards will save you time and greatly facilitate your attendance at the meeting.

. . . All high school coaches in the Twin Cities and surrounding area have been invited to hear Dr. Harvey O'Phelan and Professor Lloyd Stein discuss "Prevention and Treatment of Knee Injuries in the Athlete," a highlight of the Tuesday morning scientific session.

. . . The Association's 4th duplicate bridge tournament will begin at 9:00 p.m. on Monday night at the Saint Paul Hotel. It is open to all bridge players, duplicate experience is not necessary.

You are today where your thoughts have brought you; you will be tomorrow where your thoughts take you. — The Gilcrafter

In Memoriam

If thou expect death as a friend, prepare to entertain him; if as an enemy, prepare to overcome him. — Death has no advantage except when it comes as a stranger.
— Quarles

GEORGE L. JOYCE, M.D.

Dr. George L. Joyce, 64, Rochester physician, died March 8. He was born in Stewartville, Minnesota, and obtained his medical degree from Loyola University Medical School in Chicago. Before going to Rochester in 1935 to open up his practice, Dr. Joyce practiced in Stewartville. He was the Olmsted County deputy coroner for the past twelve years.

Dr. Joyce was a member of the Rochester Council 1013, Knights of Columbus, a member of the Zumbro Valley Medical Society, American Medical Association and Minnesota State Medical Association.

He is survived by his wife and a daughter.

FREDERIC E. B. FOLEY, M.D.

Dr. Frederic E. B. Foley, 74, St. Paul urologist, died March 24. He was born at St. Cloud and graduated from Yale University and Johns Hopkins Medical School. Early in his career, Dr. Foley was assistant pathologist at Johns Hopkins and conducted research for several years in Boston, Massachusetts.

In 1920 he established the Department of Urology at Ancker Hospital and was chief of the department until 1964. Dr. Foley invented the self-retaining bag catheter, which bears his name, in 1929 and devised a kidney surgical procedure now considered classical in urological surgery.

The American Academy of Arts and Sciences in 1955 awarded Dr. Foley the Francis Amory Septennial Award for his outstanding contributions to urology. He was a former professor of clinical urology at the University of Minnesota Medical School and practiced medicine in St. Paul from 1922 to 1960. The St. Paul-Ramsey Hospital department of urology is named in his honor.

Dr. Foley was a member of the Ramsey County Medical Society, American Medical Association and associate member of the Minnesota State Medical Association.

He is survived by a daughter.

LAWRENCE JENS KAASA, M.D.

Dr. Lawrence J. Kaasa, 86, former physician in St. Peter, died February 22. He was born in Winneshiek County, Iowa, and obtained his medical degree at the State University of Iowa, College of Medicine.

He was a member of the Freeborn County Medical Society and American Medical Association and was a 50 Club and associate member of the Minnesota State Medical Association.

He is survived by his wife and three children.

GUNNAR LINNER, M.D.

Dr. Gunnar Linner, 61, Richfield physician, died March 25. Born in Waltham, Massachusetts, Dr. Linner received his medical degree at the University of Minnesota. In 1930 he was the Stillwater prison doctor, and later headed the Anoka state hospital. Also, Dr. Linner was the physician at the Minnesota Masonic home at Savage.

He was a member of the Hennepin County Medical Society, the American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, a son and a daughter.

L. WILLIAM MORSMAN, M.D.

Dr. L. William Morsman, 82, Hibbing ophthalmologist, died March 25. He was born in Rising City, Nebraska, and graduated from the University of Nebraska, College of Medicine.

Dr. Morsman was one of the physicians responsible for organizing the medical society in the Iron Range Area forty-nine years ago. He not only was a member of that society but also was a member of the American Medical Association and a life and 50 Club member of the Minnesota State Medical Association.

JOHN WILLIAM EKBLAD, M.D.

Dr. John W. Ekblad, 91, a Duluth physician for forty-seven years and former St. Louis County coroner, died April 1 in Rock Island, Illinois, where he had resided for the past ten years. A native of Cleburne, Kansas, he graduated from the University of Kansas Medical School. He practiced medicine in Kansas until 1908 before coming to Duluth.

Dr. Ekblad retired from the practice of medicine

Continued

in 1955. He was a member of the St. Louis County Medical Society and American Medical Association, and a life and 50 Club member of the Minnesota State Medical Association. Dr. and Mrs. Ekblad would have observed their 65th wedding anniversary this summer.

He is survived by his wife and a son. Dr. Victor E. Ekblad of Superior is his brother.

HERBERT WILLIAM SCHMIDT, M.D.

Dr. Herbert W. Schmidt, 62, Mahtomedi physician and medical director of Minnesota Mining and Manufacturing Company, died April 6. A native of Northfield and a graduate of St. Olaf College, he received his doctorate in medicine from the University of Minnesota. Dr. Schmidt joined the Mayo foundation in 1934 as a fellow in surgery and was appointed to the Mayo Clinic staff in 1937. In 1948 he was named to head a section of medicine at the Clinic. He had served as president of the Clinic staff and as a member of its board of governors.

He also had served as professor of medicine at the Mayo foundation graduate school, University of Minnesota. Dr. Schmidt was a member of several professional and honorary societies including the Minnesota Thoracic Society, American Association for Thoracic Surgery, Ramsey County Medical Society, American Medical Association and Minnesota State Medical Association.

He is survived by his wife, a son and two daughters.

ALBERT L. PERTL, M.D.

Dr. Albert L. Pertl, 66, former Windom physician, died February 12. He was born in West Bend, Iowa, and obtained his medical degree from the State University of Iowa.

He practiced in Canby and was a member of the Canby school and library boards after the family left Windom twenty-eight years ago. He was a member of the Camp Release District Medical Society, American Medical Association and an associate member of the Minnesota State Medical Association.

He is survived by his wife and three children.

CHARLES N. SPRATT, M.D.

Dr. Charles N. Spratt, 91, formerly of Big Lake, Minnesota, died April 4 in Phoenix, Arizona. Born in LeSueur, he graduated from the Johns Hopkins Medical School.

He was a member of several professional societies including the Hennepin County Medical Society and American Medical Association, and was a life and 50 Club member of the Minnesota State Medical Association.

He is survived by his wife and four daughters.

ELWYN RAYMOND HUDEC, M.D.

Dr. Elwyn Ray Hudec, 55, who practiced medicine for twenty-eight years in Echo, died March 11. He was born in Winsted Township, McLeod County, graduated from Silver Lake high school and received his medical degree at the University of Minnesota.

Dr. Hudec was active in many civic and community projects, having served as mayor of Echo. He was a member of the Board of Education and the Lions International.

He was a member of the Camp Release District Medical Society, American Medical Association and Minnesota State Medical Association.

He is survived by his wife, a son and a daughter.

JOHN J. HOCHFILZER, M.D.

Dr. John J. Hochfilzer, 75, St. Paul ear, nose and throat specialist, died March 12, while on a skiing vacation in Colorado. Dr. Hochfilzer was clinical associate professor emeritus at the University of Minnesota school of medicine. He was on the staffs of St. Paul, Ramsey County and Miller hospitals.

Born in Elmau in the Tyrol in Austria, Dr. Hochfilzer received his medical education at the University of Innsbruck. He arrived here from Austria in 1923. He was the author of a number of articles in his field, and a member of the Academy of Otolarynology and the Triological Society. He was a member of the Ramsey County Medical Society, American Medical Association and a life member of the Minnesota State Medical Association.

He is survived by his wife.

"Man is of few days and full of trouble." Yet in the face of this acknowledged truth, he requests and expects that his physician will provide him with many days, and remove at least his bodily troubles.

Most men form an exaggerated opinion of the powers of medicine, founded on the common acceptation of the name, that medicine is the art of curing diseases. That this is a false definition, is evident from the fact that many diseases are incurable, and that one such disease must at last happen to every living man. A far more just definition would be, that medicine is the art of understanding diseases and of curing or relieving them *when possible*. Under this acceptation our science would at least, be exonerated from reproach, and would stand on a basis capable of supporting a reasonable and durable system for the amelioration of human maladies. — Jacob Bigelow (1787-1879)

Achievement

Meetings and Announcements

After a spirit of discernment, the next rarest thing in the world is diamonds and pearls. — Bruyere

MAY

Hennepin County Medical Society meeting, May 2 at 6:00 p.m., Pick-Nicollet Hotel, Minneapolis.

Hennepin County Psychiatric Society meeting to be held in connection with Hennepin County Medical Society Meeting on May 2.

Minnesota Society of Internal Medicine meeting, May 3 at 9:00 a.m. in Minneapolis.

Minnesota Academy of Medicine meeting, May 11 at 6:30 p.m., Town & Country Club in St. Paul.

St. Louis County Medical Society Executive Committee meeting, May 12, at 6:00 p.m., and the regular meeting at 8:00 p.m., St. Mary's Hospital in Duluth.

Minnesota Society of Clinical Pathologists meeting during Minnesota State Medical Meeting in St. Paul.

Minnesota Obstetrical & Gynecological Society meeting to be held in Rochester at the Mayo Clinic. The date to be announced.

Radiology and Pathology Departments of University of Wisconsin postgraduate course on radiology and pathology of urinary system, May 4-6, Wisconsin Center, Madison, Wisc. Contact: Thomas Meyer, M.D., 432 N. Lake St., Madison

Symposium on the Battered Child, May 13-14, University of Colorado School of Medicine, Denver. Contact: Office of Postgraduate Medical Education 4200 E. 9th Avenue, Denver.

American Cancer Society scientific sessions, St. Francis Hotel, San Francisco, May 11. Contact: Director, 219 East 42nd Street, New York. Symposium will present advances in diagnosis of common cancer sites.

JUNE

Twenty-Third Annual Meeting American Geriatrics Society, Palmer House in Chicago, June 23-24. No registration fee: Contact: Edward Henderson, M.D., 10 Columbus Circle, New York.

Minnesota Academy of Medicine President's Meeting, June 8, Town and Country Club, St. Paul at 6:30 p.m.

St. Louis County Medical Society Executive Committee Meeting, 6:00 p.m., St. Luke's Hospital in Duluth, regular meeting, 8:00 p.m.

115th AMA Annual Convention, Chicago, June 26-30. Contact: AMA in Chicago for reservations.

ANNOUNCEMENTS

Dr. Birger Strandell, a member of the faculty of the Caroline Institute, Stockholm, and editor of ACTA MEDICA SCANDINAVICA, will lecture on "Linnaeus" at Rochester, May 10, 1966. The lecture, sponsored by the Mayo Foundation chapter of Sigma XI, will be held a day before the opening of the annual meeting of the American Association for the History of Medicine. Contact: Thomas E. Keys, 200 First Street Southwest, Rochester, Minnesota.

* * *

A symposium on Liver Disease will be held in the Mayo Auditorium of the University of Minnesota May 23, 24 and 25, in honor of Cecil James Watson, M.D. Symposium is open to all physicians at no charge.

* * *

Spring Cardiopulmonary Seminar will be held at Mount Sinai Hospital, May 19, 20. Contact: Jerome T. Grismer, M.D., Mt. Sinai Hospital, Minneapolis.

* * *

Minnesota State Medical Association Meeting, May 16-17, St. Paul Hotel, St. Paul. Contact: Harold W. Brunn, Executive Secretary, 496 Lowry Medical Arts Building, St. Paul.

* * *

One day educational program for physicians sponsored by Minnesota Heart Association, May 21, 8:30 a.m. at the Radisson Hotel in Minneapolis. Contact: Marie Nelson, 1821 University Avenue, St. Paul or Dr. Reuben Berman.

* * *

Minnesota Surgical Society Annual Essay Prize to be awarded in November, 1966. Prize of $500 will be given for the best paper on a surgical subject submitted by a medical student, intern or resident. Papers directed to surgical research and papers on clinical topics are acceptable. Deadline for submission of manuscripts is August 1, 1966. Send papers to: John F. Perry, Jr., M.D., St. Paul-Ramsey Hospital, 640 Jackson St., St. Paul.

Sustained circulatory, respiratory and cerebral stimulation for the

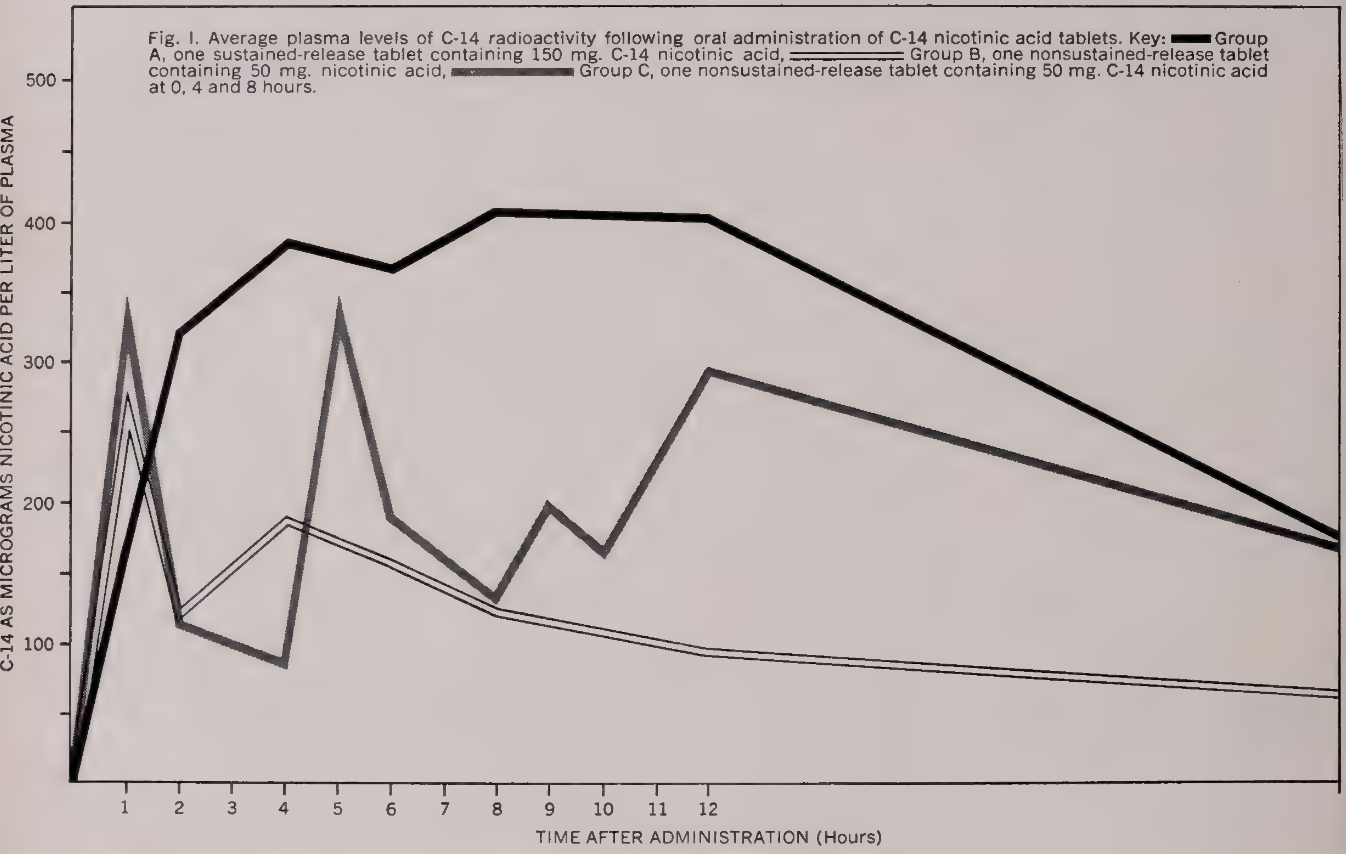

Fig. I. Average plasma levels of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ▬ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═ Group B, one nonsustained-release tablet containing 50 mg. nicotinic acid, ▬ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

(fewer absent doses by absent-minded patients)

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

aged and debilitated

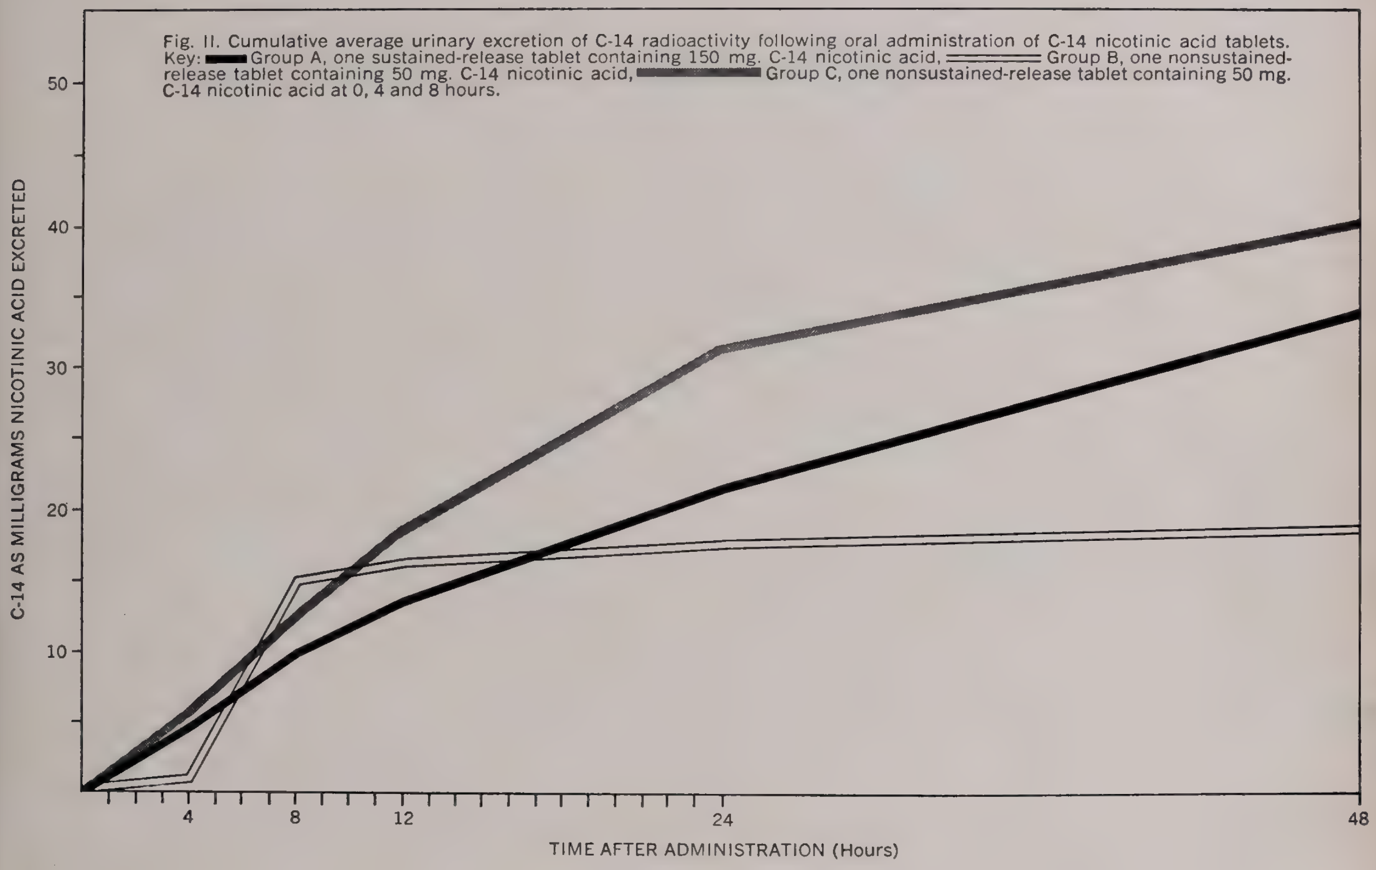

Fig. II. Cumulative average urinary excretion of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ━ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═ Group B, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid, ▬ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

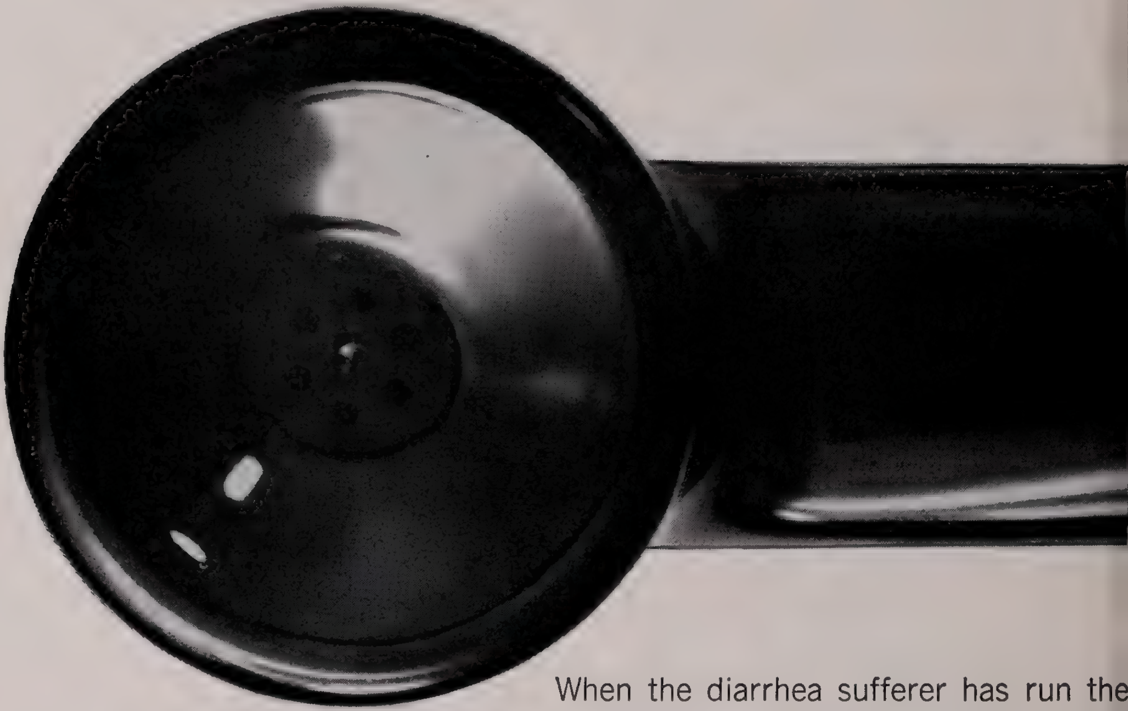
Tempotrol® Time Controlled Tablet

When uncontrolled diarrhea brings a call for help



When the diarrhea sufferer has run the gamut of home remedies without success, pleasant-tasting CREMOMYCIN can answer the call for help. It can be counted on to consolidate fluid stools, soothe intestinal inflammation, inhibit enteric pathogens, and detoxify putrefactive materials—usually within a few hours.

CREMOMYCIN combines the bacteriostatic agents, succinylsulfathiazole and neomycin, with the adsorbent and protective demulcents, kaolin and pectin, for comprehensive control of diarrhea.

Indications: Diarrhea. *Contraindications:* Kaolin: Withhold if diverticulosis is present or suspected. *Precautions:* Sulfonamide: Continued use requires supplementary administration of thiamine and vita-

Bamadex® Sequels®

Contraindications: In hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised; especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of pre-existing symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dose—operation of motor vehicles, machinery or other activity requiring alertness should be avoided. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness.

Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia, the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor, and respiratory collapse.

Bamadex® Sequels®

d-amphetamine sulfate (15 mg.) and meprobamate (300 mg.)
Sustained Release Capsules

By providing combined anorexigenic-tranquilizing action, BAMADEX SEQUELS Capsules help your nonshrinking patients to establish new patterns of eating less. The amphetamine component suppresses the appetite, while the meprobamate helps allay nervousness and tension. And for most patients, the *sustained* release of the active ingredients makes possible convenient one-capsule-a-day dosage.

Minnesota Medicine at a Glance

Immunogenesis — Good et al. Page 725

In experimental medicine the "central lymphoid tissues" offer an exciting role in both normal and abnormal immune responses in their contribution to lymphomagenesis. The manuscript of Good et al. will be worth a careful study in order to keep abreast of this new development.

Human Serum Cholesterol Synthesis — Taylor et al. Page 728

The mysteries of cholesterol metabolism can be traced by using heavy water (D_2O). Eight serum cholesterol synthesis studies were carried out on five healthy human subjects — alternating them between cholesterol-rich and cholesterol-poor diets and monitoring the cholesterol response. The studies indicate that man, unlike the dog and cat, has no "feed-back" mechanism to compensate for changes in his diet cholesterol. Endogenous cholesterol is apparently delivered to the plasma at an unaltered rate regardless of diet. Physicians caught up in the continuing cholesterol controversy will find this article absorbing.

Hyperparathyroidism and Hypercalcemic Crises — Flink et al. Page 734

Hyperparathyroidism masquerading as a variety of diseases can produce acute and sometimes fatal illness. The clinical evaluation and laboratory tests are significant in making an accurate diagnosis. In any individual in whom there is profound muscular weakness and progressive hypotension there is usually associated nausea, vomiting, weight loss, lethargy, confusion, abdominal pain, polyuria, polydipsia, and constipation, with the emphasis resting on muscular, gastrointestinal, and mental symptoms which have a tendency to occur in a hypercalcemic crisis.

Four cases of this dramatic disease have been described by Flink et al.

Lung Function — Ebert Page 745

In pulmonary emphysema there is destruction of the normal architecture of the lung, alveolar septa are lost, and the normal air spaces are replaced by larger air-containing structures of variable size. This results in diminution of the diffusing capacity and the surface area to which blood and oxygen can be exposed. Resistance to air flow which is dependent on the velocity at which the air passes over the available space, and bronchial obstruction which is in turn dependent upon the pressure between the alveoli and and the lumen of the bronchus can also contribute to pulmonary incapacity. Any disease which modifies the magnitude of these structures will result in malfunction of the lungs.

Macroglobulins — Bell and Neumann Page 753

Bell and Neumann review their experiences with eight cases of macroglobulinemia. To detect the presence of macroglobulins they used paper and starch gel electrophoresis, the Sia test, dissociation of globulins with penicillamine, and ultracentrifugation. Seven patients had varying combinations of liver, spleen, and lymph node enlargement. One was referred with a diagnosis of lupus erythymatosus. All demonstrated excessive lymphocytes or atypical mononuclear cells in their marrow, and all had elevated sedimentation rates. The authors conclude that the most reliable tests are paper electrophoresis, immunoelectrophoresis with gamma IM antiserum, penicillamine disassociation, and ultracentrifugation.

Transfusions in Auto-Immune Hemolytic Anemia
— Yunis and Bridges Page 759

In auto-immune hemolytic anemia it is frequently difficult to obtain a perfect crossmatch. Additional laboratory studies must be carried out to find the least incompatible blood for transfusion.

Yunis and Bridges collect 40 patients with auto-immune hemolytic anemia. They describe their techniques in searching for etiologies. This manuscript gives a compact description of a technically baffling problem.

Sequelae of Prematurity — Branthaver Page 803

The sequelae of prematurity are often not observed until the child begins to function and associate more extensively with her peers. The only finding in this six-year-old girl was that of spasticity of the lower extremities which did not interfere with her ambulation except to give her a clumsy gait. In evaluating this girl's various skills it was found that she was slightly below average in some phases but a bit above average in others. She found it difficult to follow directions for abstract tasks, and she was considered to be in the low educable mentally retarded range.

After studying this child in conference, it was decided that management of her educational program would rest with the school authorities in cooperation with the mother.

Gastrointestinal Scleroderma — Grand Rounds Page 827

Previously, scleroderma has been considered to be primarily a dermatologic disease, but in recent years systemic manifestations, principally in areas of the gastrointestinal tract, have become evident. Dermatologic manifestations are not always evident, but when progressive dysphasia and articular pains develop, one should be suspicious of this condition. A variety of treatments have been found to provide partial relief.

Normal Values — Alexander Page 851

The normal ranges for most laboratory values are based on different samples of the populations and vary from hospital to hospital and from textbook to textbook. The clinician may find himself faced with a dilemma when he is presented with a normal value. This paper shows why normal isn't necessarily normal.

Derivatively Speaking

Gout — from Latin *gutta* (a drop, because the ancients believed the disease was due to a noxa falling drop by drop into a joint)

Brewer Diagnostic Kits

Complete Serological Screening Tests For Syphilis . . .

The RPR Card Tests make use of a specially prepared, carbon-containing RPR Card antigen. The particle size and other characteristics of the carbon is such that when a reactive specimen is encountered, flocculation occurs, and there is a coagglutination which is readily visible to the naked eye. Individual tests, including the collection of blood and separation of plasma can be performed in 7 to 8 minutes.

Confirming earlier findings with the RPR Card Test[1-10] Reed[11] in reporting on 63,800 specimens had an overall agreement of 98.5% in a recent comparative study with other routine screening procedures.

The RPR Card Tests, with their low cost, ease of performance, high sensitivity and specificity, are without peer in situations that demand rapid testing of patients, enabling the physician to initiate prompt treatment of early infectious syphilis.

Specify the RPR Card Test as the screening procedure on serum or plasma samples submitted to your State Approved Laboratory.

NTZ Nasal Spray relieves hay fever symptoms on contact

Fast symptomatic relief from seasonal hay fever comes in the convenient NTz Nasal Spray bottle. Two sprays quickly relieve itching and decongest the nasal membranes on contact. The first spray of NTz shrinks the turbinates, helps restore normal nasal ventilation and breathing. After a few minutes a second spray enhances sinus ventilation and drainage.

NTz Nasal Spray reduces excessive rhinorrhea without unpleasant dryness. It is well tolerated by delicate respiratory tissues. NTz also provides relief in head colds, perennial rhinitis and sinusitis.

NTz's carefully balanced formula relieves three ways: with a decongestant, a topical antihistamine, and an antiseptic wetting agent.

Neo-Synephrine® HCl 0.5%, a decongestant of unexcelled efficacy to shrink nasal membranes.

Thenfadil® HCl 0.1%, a topical antihistamine to help relieve itching.

Zephiran® Cl 1:5000, an antiseptic wetting agent to promote the rapid spread of components to less accessible nasal areas.

NTz is supplied in leakproof, pocket-size, spray bottles of 20 ml. and in bottles of 30 ml. with dropper.

Winthrop Laboratories, New York, N. Y. 10016

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

Anatomy of
Low Back Pain #1
the sedentary life
is often the seat of
low back pain

The human spine is not engineered for prolonged sitting at desks, pianos, typewriters and drafting boards. The stresses set up by the heavy, forward-tilted head and trunk, balanced precariously on an insufficient base, result in strain of the dorsal musculature, particularly at the low lumbar level.

The unusual muscle-relaxant and analgesic properties of 'Soma' make it especially useful in the treatment of low back sprains and strains. 'Soma' is widely prescribed ☐ **to relieve pain** ☐ **to relax muscles** ☐ **to restore mobility.**

Indications: 'Soma' is useful for management of muscle spasm, pain, and stiffness in a variety of inflammatory, traumatic, and degenerative musculoskeletal conditions. It also may act to normalize motor activity in certain neurologic disturbances.

Contraindications: Allergic or idiosyncratic reactions to carisoprodol.

Precautions: 'Soma', like other central nervous system depressants, should be used with caution in patients with known propensity for taking excessive quantities of drugs and in patients with known sensitivity to compounds of similar chemical structure, e.g., meprobamate.

Side Effects: The only side effect reported with any frequency is sleepiness, usually on higher than recommended doses. An occasional patient may not tolerate carisoprodol because of an individual reaction, such as a sensation of weakness. Other rarely observed reactions have included dizziness, ataxia, tremor, agitation, irritability, headache, increase in eosinophil count, flushing of face, and gastrointestinal symptoms.

One instance each of pancytopenia and leukopenia, occurring when carisoprodol was administered with other drugs, has been reported, as has an instance of fixed drug eruption with carisoprodol and subsequent cross reaction to meprobamate. Rare allergic reactions, usually mild, have included one case each of anaphylactoid reaction with mild shock and angioneurotic edema with respiratory difficulty, both reversed with appropriate therapy. In cases of allergic or hypersensitivity reactions, carisoprodol should be discontinued and appropriate therapy initiated. Suicidal attempts may produce coma and/or mild shock and respiratory depression.

Dosage: Usual adult dose is one 350 mg. tablet three times daily and at bedtime.

Supplied: Two Strengths: 350 mg. white tablets and 250 mg. orange, two-piece capsules.

Before prescribing, consult package circular.

for the relief of low back sprains and strains

President's Letter

"You may be right" and no buts will be added.

Several letters, and quite a few conversations, make it obvious that there are a number of physicians sincerely opposed to some Association policies, and concerned that no avenue of communication is open between them and Association membership.

It has never been Association practice to mute any voice of dissent, but it may be that the usual avenues, Reference Committee attendance, House of Delegate participation, or appearance before the Council are too technical, too formal, or inappropriate in time.

Consequently, after discussion with Dr. Carl O. Rice, Editor, MINNESOTA MEDICINE is introducing a new section, experimental in a sense, provocative in approach, and directed to what appears to be a need; a forum for member expression in print.

It is well to note the challenge in the title of this new section — "You May Be Right" — a challenge to consider, to weigh, and to be factually sure before committing any opinion to the judgement of the readers.

Now that motherhood is losing to the expanding claims of competing pill makers, and sin, not adopting new faces, is only exposing old breasts, areas of previous total agreement are obviously decreasing. But following Federal intervention in patient care in a manner never dreamed of by the Congress which made the act a law, many new situations creating strong, and strongly diverse, opinions are developing.

Certainly, any statement of Association policy must represent the consensus, but it seems logical that some opportunity should be provided for the minority who disagree, and want to explain the basis for that disagreement.

The potentials of this new venture are as wide as medical interests, are not restricted to any area, and have no boundaries other than reader interest and good judgement on the contributors part.

The use of space, and the determination of reader appeal are a matter of editorial judgement. Editing, condensing and possible rejection will be, as always, editorial prerogatives. Familiarity with the high standards of MINNESOTA MEDICINE is, however, an assurance that the same standards will apply to this new venture.

R P Buckley M.D.

R. P. Buckley, M.D.
President
Minnesota State Medical Association

must penicillin
be a bitter pill
to swallow?

Not if it is V-Cillin K.

V-Cillin K now has a unique glossy coating that banishes bitter penicillin taste and makes it easier to swallow. Within six seconds (just long enough for the tablet to get past the taste buds), the coating dissolves and the penicillin is ready for immediate absorption into the bloodstream. The patient still gets all the special benefits of V-Cillin K, including consistent dependability . . . even in the presence of food.

Indications: V-Cillin K is an antibiotic useful in the treatment of infections caused by streptococci, pneumococci, and sensitive strains of staphylococci.

Contraindications and Precautions: Although sensitivity reactions are much less common after oral than after parenteral administration, V-Cillin K should not be administered to patients with a history of allergy to penicillin. As with any antibiotic, observation for overgrowth of nonsusceptible organisms during treatment is important.

Usual Dosage Range: 125 mg. (200,000 units) three times a day to 250 mg. every four hours.

Supplied: Tablets V-Cillin K, 125 or 250 mg.; also, V-Cillin K, Pediatric, 125 mg. per 5-cc. teaspoonful, in 40, 80, and 150-cc.-size packages.

V-Cillin K® Six-Second Barrier to Bitterness

Potassium Phenoxymethyl Penicillin

Primary Aldosteronism

GEORGE M. B. HAWLEY, M.D.
Red Wing, Minnesota
LOUIS TOBIAN JR., M.D.*
Minneapolis, Minnesota

IN JULY OF 1962 there were 205 published or well documented cases of primary aldosteronism. Since that time there has been a great increase in the rate of detection of this syndrome throughout the world, and it is estimated that the number of established diagnoses is now many hundreds.[1] This communication reports the unmasking of the clinical features of this condition by the administration of a thiazide diuretic. It also deals with the problem of residual hypertension after an aldosteronoma has been removed.

Case Report

The patient was a 46-year-old single white female with a background of general good health aside from symptoms of nervousness and anxiety. Her 80-year-old mother had essential hypertension. On a routine physical examination in 1949, at age 32, the patient's blood pressure was 140/88. Facial acne and a seborrheic dermatitis of the trunk were noted. An excess of coarse black hair was present on the forearms and legs and there was a male escutcheon. The urine specific gravity was 1.026 and the pH 8.0. At age 37 her blood pressure was 156/94; at age 44 it was 210/108. She was not seen again until age 45 (1962). On six occasions during a subsequent eight-month period, her blood pressures varied from 212/106 to 224/120. On two occasions she was placed on a reserpine-thiazide preparation for one month, with no significant symptomatic response or change in her blood pressure levels. On 10-27-62, because of the hypertension, hirsutism, and facial acne, she was referred by her gynecologist to one of us to rule out the possibility of Cushing's syndrome. Her urine 17 ketosteroid and 17 hydroxycorticosteroid levels were normal. She was given a preparation containing 4 mgm. of trichlormethiazide and 1/10 mgm. of reserpine to be taken twice daily. Seven days later she noted the onset of progressive and pronounced weakness in both lower extremities, so severe that she fell to the floor when she attempted to stand. There was associated severe aching in the legs and intermittent paresthesias in both hands. On physical examination her blood pressure was 214/112. Generalized deep tendon hyporeflexia was present. At this time the possibility of a diagnosis of primary aldosteronism was considered. Her antihypertensive medication was discontinued and she was placed on supplemental potassium with prompt symptomatic and objective improvement. Ten days later, while still on supplemental potassium, her serum potassium level was 2.6 mEq/L., the serum chloride 97 mEq/L, and the sodium 143 mEq/L. Repeated urine examinations revealed a persistent alkalinity. Her kidneys were unable to concentrate the urine above a specific gravity of 1.015. She recalled that in recent months she had noted a moderate nocturnal polyuria. Two urine aldosterone determinations were reported as 35 mcg.% and 39 mcg.% (normal 3-32 mcg.%).

Laboratory Studies

The patient was referred to the service of one of us at the University of Minnesota Hospitals for confirmation of the presumptive diagnosis of primary aldosteronism. Further laboratory determinations at that hospital revealed the following values: blood urea nitrogen 8 mg.%, blood creatinine 0.8 mg.%, standard creatinine clearance 151/L in 24 hours, bicarbonate 36 mEq/L, chloride 97 mEq/L, sodium 144 mEq/L, and potassium 2.5 mEq/L. Serial daily potassium levels were in the range of 2.1 to 2.5 mEq/L. A blood volume determination done by the radioactive iodinated albumin technique was 5.9 liters. A chest film, electrocardiogram, and intravenous pyelogram were all within normal limits. A urine culture was sterile. Bilateral ureteral catherizations were performed to carry out a Rappaport test. This was considered to be normal and there was no evidence of renal arterial constriction. The serum calcium was 8.7 mg.% and the serum phosphorus 2.8 mg.%.

---

*Professor of Internal Medicine, University of Minnesota School of Medicine.

A glucose tolerance test was interpreted as borderline diabetic. Two urinary 17 hydroxycorticosteroid levels were within normal limits.

The patient was started on large doses of supplemental potassium, up to 16 gm./day, and at the end of a week her serum potassium had risen from 2.8 to 5.1 mEq/L with a drop in bicarbonate to 23 mEq/L, and the appearance of an acid pH of the urine.

Operative Findings

On 12-10-63, using an anterior bilateral subcostal approach, the right adrenal gland was carefully dissected free and found to be normal to palpation by Dr. Richard L. Varco, Department of Surgery, University of Minnesota School of Medicine. A tumor 1.2 cm. in all diameters was located in the left adrenal, and a total left adrenalectomy was performed. The patient had a postoperative diuresis of 3,000 cc. on the first postoperative day, with volumes during the next seven days ranging between 2700 cc. and 3500 cc. Nine days postoperatively her serum potassium was 4.2 mEq/L, serum sodium 137 mEq/L, and bicarbonate level 26 mEq/L.

Pathologic Findings

The pathologist's examination of the excised nodule describes "a sharply circumscribed encapsulated round nodule composed of cords and columns and nests of rather large cells arranged in a rooftile pattern, these cells having abundant, mostly clear, somewhat granulated cytoplasm, and round, small, nuclei with a distinct fine chromatin network. There is some variation in nuclear size and outline. The cells are subdivided into small lobules by very delicate connective tissue septa containing small and large blood channels. The appearance is that of a cortical adenoma of the adrenal gland and presents no features which might indicate its metabolic activity" (Figures 1 and 2).

Postoperative Course

The patient returned to her home two weeks after surgery but was hospitalized two days later because of the development of a hematoma in her right thigh. During the following eight days her blood pressure ranged from 136/74 to 160/110. She had lost 18½ lbs. in her immediate postoperative period and now weighed 123 lbs. On 1-8-64 her blood pressure was 162/106. The urine pH was 4.5 with a specific gravity of 1.018. On 2-3-64 the blood pressure was 186/120, and eight subsequent readings taken at intervals of one month ranged from 168/102 to 196/110. A urine concentration determination on 6-15-64 revealed a maximum specific gravity of 1.021 and her serum potassium was 5.1 mEq/L. On 9-22-64 she was placed on 1.5 gm. of chlorothiazide* daily and continued on a low sodium diet. Her serum potassium one week later was 3.7 mEq/L. On 9-29-64 her dosage of chlorothiazide was increased to 2 gm. per day. Her serum potassium on 10-17-64 was 4.0 mEq/L. Subsequent blood pressure readings at intervals of one month ranged from 148/98 to 160/100 mm. of mercury. On 5-20-65 the patient was asymptomatic and her urine pH was 5.0 with a specific gravity of 1.019. The 8:00 a.m. plasma cortisol level was 16 mcg.% and the 8:00 p.m. specimen less than 5 mcg.%. The BUN was 18 mgm.%, creatinine 1.3 mgm.%, uric acid 8.0 mgm.%, bicarbonate 30, chloride 99, sodium 137, and potassium 3.7 mEq/L. It was felt that the modest hypokalemia and hyperuricemia were probably due to the use of chlorothiazide to control her hypertension.

Discussion

The symptoms and signs of primary aldosteronism have been clearly defined and are attributable to (1) potassium depletion, (2) hypertension, and (3) hyposthenuria. The clinical manifestations are usually vague and seldom clear-cut unless accelerated potassium depletion is effected by diminished intake, gastrointestinal losses, or as in our case, increased renal loss after the administration of a thiazide diuretic. In the patient presented here, the thiazide acted as a provocative test for primary hyperaldosteronism. This may prove to be a useful procedure in other suspected cases. Metabolic alkalosis is usually present along with elevated values of aldosterone secretion.

---

*Diuril®

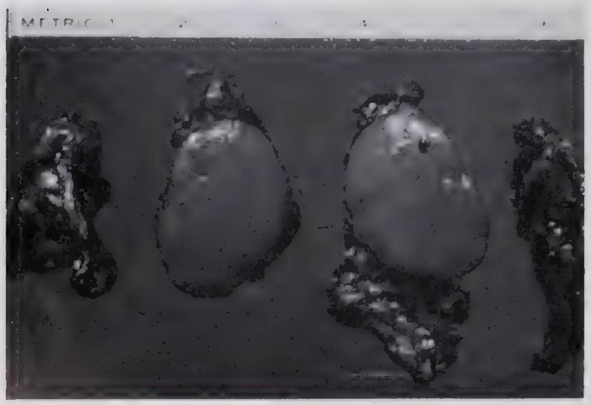

Fig. 1 — Surgically excised adrenal tissue showing the aldosterone-secreting adenoma.

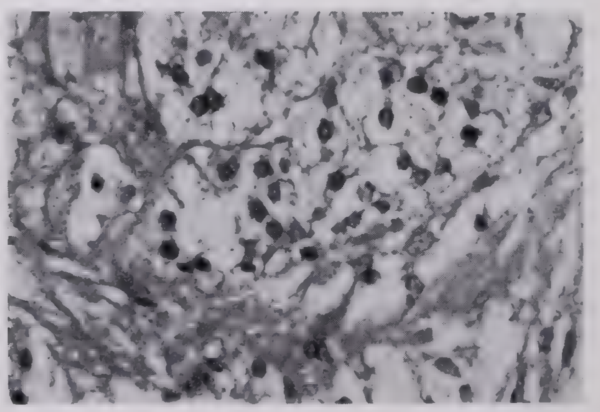

Fig. 2 — Photomicrograph of aldosterone-secreting adenoma.

Before adrenalectomy is performed, hyperaldosteronism secondary to renal vascular hypertension, malignant hypertension, nephrosis, cirrhosis, and cardiac insufficiency should be carefully considered. In most hypertensive patients with secondary aldosteronism the serum sodium is either normal or low, and alkalosis, if present, is usually mild. In hypertension with secondary aldosteronism, the serum potassium level is usually between 3 and 4 mEq/L. In the hypertension of primary aldosteronism, the serum potassium is usually below 3 mEq/L. Conn[2] states that in primary aldosteronism the secretion of renin is severely depressed, whereas in aldosteronism secondary to renal vascular disease renin activity is increased. He feels that eventually renin levels will be used effectively to differentiate these two conditions.

The extreme importance of effecting potassium balance prior to adrenalectomy has been emphasized by Zimmerman and others.[3] A case has been reported where over a period of eight years potassium supplements of 8-12 gm. daily were able to maintain normal serum potassium levels and the patient in a symptom-free state.[4]

After the removal of the adenoma in our patient, the tendency to severe hypokalemia disappeared even when large doses of thiazide were given. Moreover, the pH of the urine ceased to be continuously alkaline, and the ability to form a concentrated urine was restored. The level of arterial pressure was also reduced but still remained in the hypertensive range. This residual hypertension can be accounted for either by an underlying essential hypertension which preceded the aldosteronoma or by the appearance of "metacorticoid" hypertension, or by both. The term, "metacorticoid hypertension" is used to describe a hypertensive syndrome in rats. If a rat receives desoxycorticosterone and salt for only six weeks and becomes hypertensive, removal of the desoxycorticosterone and salt usually allows the blood pressure to return to normal. However, if the desoxycorticosterone and salt are administered for as long as five months, the hypertension may persist indefinitely even after the desoxycorticosterone and salt regimen has been discontinued.

The hypertension which results in man from an aldosterone-secreting adenoma resembles desoxycorticosterone hypertension in the rat. Therefore, the residual hypertension which is present following removal of an aldosteronoma may be the human counterpart of "metacorticoid" hypertension in the rat.

An Overestimate?

There are men and classes of men that stand above the common herd; the soldier, the sailor, and the shepherd not infrequently: the artist rarely; rarelier still, the clergyman; the physician almost as a rule. He is the flower (such as it is) of our civilization. . . . Generosity he has, such as is possible only to those who practise an art, never to those who drive a trade; discretion, tested by a hundred secrets; tact, tried in a thousand embarrassments; and what are more important, Herculean cheerfulness and courage. — Robert Louis Stevenson (1850-1894)

Prejudice is being positive about something negative. — Phoenix Flame

Congenital Hip Subluxation

RAMON B. GUSTILO, M.D.[**]
RICHARD CUSHING, M.D.[**]
ARNOLD S. ANDERSON, M.D.[**]
Minneapolis, Minnesota

THE DIAGNOSIS of congenital hip dysplasia in the first six months of life leads to effective and successful management of this difficult problem. Early diagnosis is possible only if the initial findings are clearly understood by the examining physicians of the newborn child and if follow-up is maintained throughout the first twelve months of post-natal care.

The published works of Vernon Hart,[9] H. R. McCarroll,[13] and L. E. Harris et al.[8] provide an excellent criterion for the early diagnosis of congenital hip dysplasia. Recent studies[1,2,4,22] have shown that the primary anatomical defect is in the laxity of the capsule. This laxity may be due to hormonal factors, which subsequently develop into either congenital subluxation or dislocation of the femoral head. The generally accepted theory that inadequate acetabulum is the primary cause has been found to be incorrect by arthrogram studies, as pointed out by Mitchell[14] and Somerville.[19,20] We[11] have verified the Somerville findings through our own arthrogram study and by dissection of acetabula in fetuses of many ages. Evidence tends to show that shallow acetabulum and excessive femoral anteversion are the results of subluxation or dislocation.

Hip dysplasia is divided into two categories, *subluxation* and *dislocation.* Subluxation is defined as upward or lateral displacement of the femoral head, where motion still occurs between the femoral head and the acetabulum. Complete dislocation is a type of hip dysplasia in which the femoral head is completely out of the acetabulum. According to Somerville, in subluxation the acetabulum is still the fulcrum around which movement takes place; but in a dislocation, it is not.

In the newborn child, the most reliable guide or sign of hip dysplasia is *limitation of abduction.* It is not unusual to find a limitation of 30 degrees up to the age of six months in normal hips. However, if the limitation of abduction exceeds 30 degrees or

and Dislocation in Early Infancy*

Management
of

more to assume complete abduction of 90 degrees, the finding warrants roentgenographic examination. Inequality of leg length, abnormal thigh and gluteal creases are inconstant findings in subluxation; in complete dislocation, limitation of abduction, shortening of the affected leg, and positive Ortolani[15] click are diagnostic findings. It is not unusual to have full abduction in complete dislocation, as the femoral head is either completely free of the joint or is relocated in the process of abduction. Anteroposterior projection, frog-leg position, and, sometimes, the Van Rosen[15,16] view, if necessary, usually confirm the diagnosis. The Van Rosen view is an anteroposterior projection taken with the hip in at least 45 degrees of abduction and 15-30 degrees of internal rotation. It is important to note that one must not relocate the femoral head during the process of abduction and internal rotation. If on this view the axis of the femoral neck is found to point to the anterosuperior iliac spine, or superior to it, the femoral head is dislocated.

This study is an analysis of 103 patients, 85 females and 18 males, treated at the St. Louis Park Medical Center, Minneapolis, Minnesota, in a twelve-year period (1952-1964). The current study of all the charts and x-rays available produced data on 84 subluxations and 19 dislocations. Of the 84 subluxations, 82 cases or 97 per cent were diagnosed below six months of age; 61 patients or 73 per cent were diagnosed in the first three months of age. In congenital dis-

location, the average age of diagnosis was found to be seven months. In 15 infants who were primarily seen at the St. Louis Park Medical Center since birth, the average age of diagnosis was 3.9 months (Table 1 and 2).

Diagnostic Signs

Abduction Test

The abduction test is the most reliable examination for detecting hip dysplasia in the newborn child (Table 3).[8] This test is done by laying the infant flat on his or her back on a firm examining table. With the thigh and knees flexed at 90 degrees, the hips are abducted. Ninety-six out of the 103 patients were found to have limited abduction. Three patients with dislocation had normal abduction. The other four had shortening of one leg, abnormal thigh creases and normal abduction.

Ortolani Click

Ortolani and Barlow described the click as a pathognomonic sign of congenital dislocation of the hip in infants from birth to a year old. In this test the child is laid on his back with hips flexed at right angles and knees flexed. Then the hips are slowly abducted, and somewhere in the 90-degree arc of abduction, a click is elicited as the femoral head slips back into the acetabulum. In our study, 68 per cent of the 19 dislocations had a positive click; only three cases of subluxation were found with a positive Ortolani sign. The x-rays of the latter patients indicated subluxation rather than dislocation.

TABLE 3

Incidence of Limited Abduction, Leg Shortening, Abnormal Crease and Ortolani Click in 103 Cases

Limited Abduction	96 or 95%
Leg Shortening (Allis Sign)	14 or 13%
Abnormal Gluteal or Thigh Creases	7 or 6.8%
Ortolani Click Dislocation	13 of 19 or 68%
Ortolani Click Subluxation	3 of 84 or 2%

Follow-up and Results

Follow-up	Subluxation	70 Patients, 12-84 Months 10 Patients, Less Than 1 Year 4 Patients Lost to Follow-up
	Dislocation	13 Patients, 18-72 Months (Average 35.8) 6 Patients, Less Than 18 Months
Results	Subluxation:	66 of 70 Patients - Normal Hips by Clinical Examination and Roentgenographic Criteria 4 Patients - Minimal Subluxation
	Dislocation:	12 of 13 Patients, Normal Hips 1 Patient, Minimal Subluxation

Shortening: The Allis Sign

Out of 103 cases 13 per cent were found to have a shortening of the affected limb. There were two cases of subluxation and 12 of dislocation. This test is done by laying the infant flat on his back with the knees and hips flexed 90 degrees. The sign is positive if the affected thigh is shorter than the opposite thigh. Comparing the level of the soles of the feet is fraught with errors, as the pelvis may be tilted from other causes or inadvertently tilted during the examination, thus giving a false positive sign.

Abnormal Crease

Only seven out of the 103 patients were found to have an abnormal crease either in the thigh or gluteal folds. The low incidence in this series probably results from the fact that the examining physician did not make a notation or did not pay particular attention to this sign.

Radiologic Diagnosis

Interpretation of x-rays is difficult in the first six months of age because of the absence of the femoral head. Ninety of the patients had x-rays available for study; in the remaining cases the diagnosis was taken from the radiologist's report. Four criteria were noted in the anteroposterior projection, as illustrated in Figure 1.

1. *Acetabular angle.* The acetabular angle was measured by the Hilgenreimer[10] method, before the onset of treatment, after treatment, and on the final follow-up x-rays.

2. *Presence or Absence of the Capital Epiphysis.* This is of little value in the first six months, because it is seldom evident at this time. However, in following a patient's case,

a delay in appearance compared to the normal side or inequality of size is considered corroborative evidence of congenital hip dysplasia.

3. *Shenton's Line.* In a normal hip, this is an arc formed by the inferomedial border of the neck of the femur and the superior border of the obturator foramen. A break in this line occurs when the femoral head or neck rides superiorly, laterally, or both, in relation to the acetabulum.

4. *Direction of the Central Axis of the Head and Neck or Femoral Neck in Relation to the Acetabulum.* No measurement was made in this method except by direct visualization.

There were 84 subluxations (two or more positive roentgenographic criteria) and 19 dislocations.

In the cases studied, the acetabular angle averaged 32 degrees (20 to 43) in the affected hip, while the normal hip averaged 23 degrees (12 to 31). Seventy-seven per cent of the cases were found to have increased acetabular angle, when compared to the normal hip. Caffey's[5] study shows a much greater variation in the acetabular angle in normal infants. The important thing to be noted, however, is the inequality of the acetabular angles in the same infant and its correlation with the clinical findings. The acetabular angle reflects only the osseous development of the acetabulum. Our arthrogram study and fetal dissections showed that the acetabulum covered the femoral head adequately in spite of an apparent shallow acetabulum in anteroposterior projection roentgenograms (Figures 2-a and 2-b).

Eighty-one per cent of the 103 cases had an abnormal Shenton's line.

Of the 84 subluxations, 24 per cent have been noted to have delayed, smaller, or absent capital epiphyses compared to the opposite normal hip on the initial x-rays. Of the congenital dislocations, 52 per cent have delayed or smaller capital epiphyses.

Eighty-nine per cent were found to have deviation of the central axis of the femoral head and/or neck from the center of the acetabulum.

Management

Hip Subluxation

For subluxations, an abduction pillow splint (a modified Frejka splint) made by the parents under the guidance of the pediatric nurse has been most successful. The average duration of treatment is 4.4 months, with a range of one to 15 months. This usually involves the continuous use of a pillow splint for three months, followed by one month in which it is applied only during the night and long napping times. Termination of the use of the splint is based upon both clinical and x-ray findings; the x-ray criteria

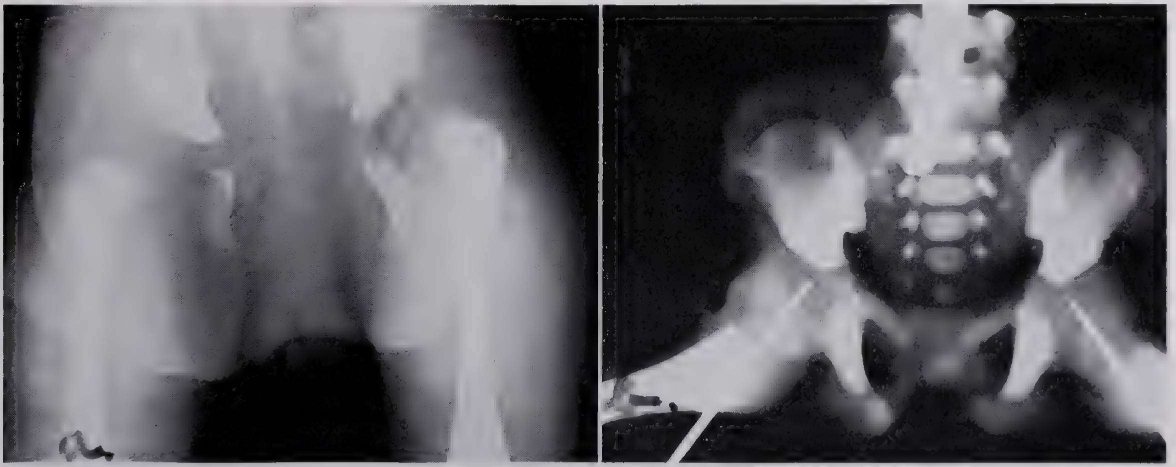

Fig. 2(a) — Anteroposterior roentgenogram of both hips of a dead fetus, showing complete dislocation of the left hip. The acetabular angle is markedly increased. (b) — Anteroposterior roentgenogram of both hips in the same fetus illustrates the vacuum phenomenon effect. There is a radiolucent area around the capital epiphyses and shows an excellent covering of the femoral head by the acetabulum.

are normal acetabular angles, central axis of the femoral head and neck well-centered in the acetabulum, and the capital epiphysis covered by at least three fourths of the acetabulum.

Congenital Dislocation

The treatment of congenital dislocation involves the following steps:

1. Preliminary traction for about 10 days to two weeks, unless the dislocation is noted in the first three months when the femoral head can be relocated easily. The traction is continued and maintained for several days, until the femoral head and neck are level with the inferior edge of the acetabulum.
2. Application of bilateral spica cast in frog-leg position. Adductor tenotomy should be done whenever the adductors are felt to be tight.
3. After three to four months in a bilateral spica cast, the infant is placed in a single spica cast in Lange's position for another eight to twelve weeks.
4. Upon removal of the cast, an abduction bar is applied with the hips at 45 degrees to each other and maintained for several weeks. The use of the abduction bar is then reduced to night-time application only and is finally discontinued when the hips appear normal by roentgenogram.
5. Derotation osteotomy may be necessary when femoral anteversion is excessive and persists.
6. These children should be followed for several years — at least until cessation of growth.

The average duration in a cast is seven months (3 to 18) and nine months in an abduction bar (3 to 24 months). Only one patient needed an open reduction to correct the dislocation; another required a derotation osteotomy to correct excessive anteversion of the femoral head and neck.

Arthrography

The arthrogram was employed in the last six congenital dislocations seen at the Medical Center to ascertain the accuracy of reduction and to determine the presence of intra-articular obstacles in the acetabulum. These are usually difficult to find on routine x-rays because of the absence of the femoral head. There are possible intra-articular obstacles, such as an hourglass labrum, a hypertrophied ligamentum teres, and an infolding of the capsule as reported by O. Scaglietti and B. Callandriello.[18] If such obstacles are present, preventing closed reduction of the dislocated hip, then open reduction and removal of the obstacle is advised. Thirty-three per cent Hypaque solution is used for arthrography; the amount usually required is 2 to 3 c.c. Interpretation requires experience and understanding of possible intra-articular obstacles to prevent false positive readings as shown in Figures 3-a and 3-b.

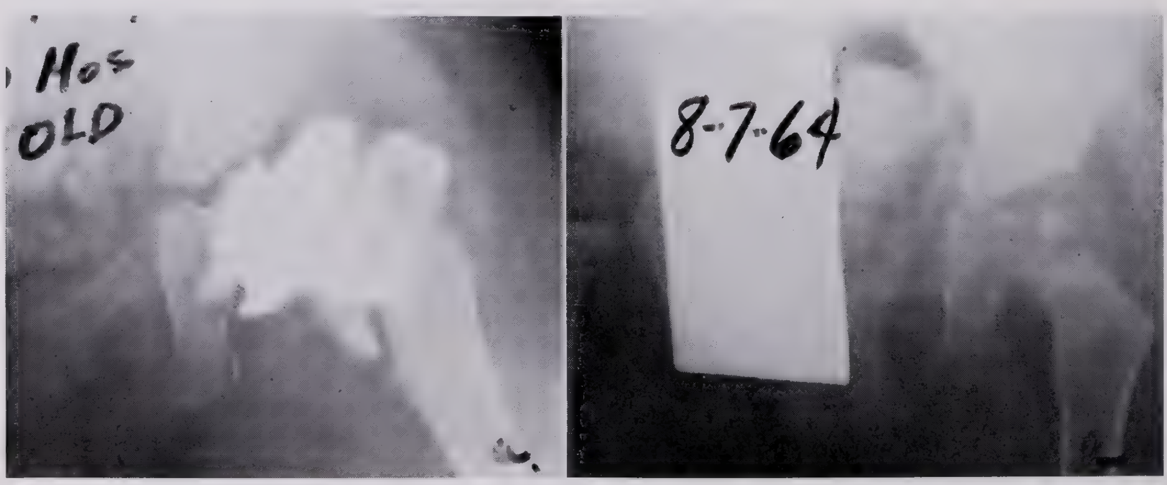

Fig. 3(a) — Arthrogram of the dislocated left hip in a 10-month-old girl showed a possible "hourglass defect" of the labrum or an infolding relaxed and redundant capsule. (b) — Five months later after closed reduction, AP roentgenogram showed the femoral head well seated in the acetabulum. The defect in the arthrogram represents an infolding capsule rather than a true hourglass labrum.

Results

Of the 84 subluxations, on the latest follow-up of 70 patients, 94 per cent have normal hips by roentgenogram. These patients were followed from twelve to eighty-four months after cessation of treatment. X-rays still indicate a minimal subluxation in four of the children after 12, 20, and 22 months of the follow-up. One patient developed a coxa vera, (Table 4).

Dislocation

Twelve out of 13 patients who had a dislocation have normal hips by x-rays and clinical examination after an average follow-up of 35.8 months (range of 18-72 months). One patient has a very minimal subluxation on x-ray, although clinically normal. This may be a case where early degenerative arthritis will develop. One child developed a valgus knee which is probably secondary to prolonged abduction bar, as this particular patient was in an abduction bar for fifteen months. To avoid this sequela, an abduction bar has been devised* which eliminates the valgus stress placed on the knee by the ordinary bar (Figure 4). Two years after treatment as has been outlined, one patient developed an aseptic necrosis of the femoral head in the same hip. This was difficult to differentiate from Legg-Perthes disease. The child was placed on an ischial weight-bearing brace until the capital epiphysis became fully revascularized.

Discussion

This study confirms the opening hypothesis that early diagnosis and adequate treatment is the key to an effective management of the congenital hip dysplasia. The real answer to the efficacy of our treatment, however, will be known forty to fifty years from now, when we can answer the question, "How many of these patients will develop degenerative arthritis secondary to a dysplastic hip?"

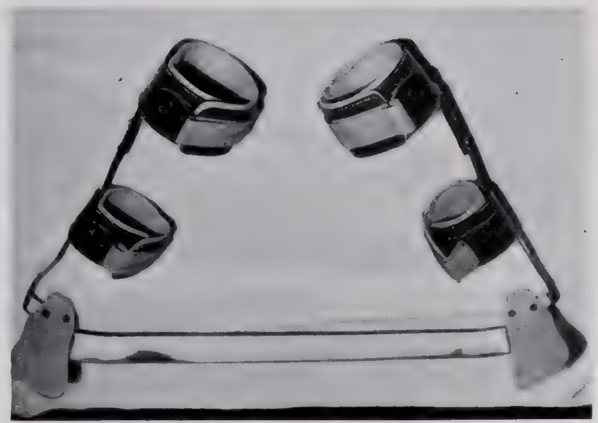

Fig. 4 — Indeck's Abduction Bar for congenital dislocation of the hip. This prevents valgus stress in the knee and allows the foot pieces to be turned in any rotation desired.

According to various studies, the casual relationship between osteoarthritis and hip dysplasia is alarmingly high, ranging from 20 to 48%.[7,12,21] For this reason, all subluxations, however minimal, and dislocations should be treated adequately until all criteria of a normal hip are attained. There are cases of spontaneous normalcy of a subluxed hip, but there is no way of telling which hip will become normal without treatment.

In cases of frank dislocation, the parents should be made aware at the start that treatment and care will be prolonged and will demand a great deal of patience on their part. These cases should be referred immediately to the care of an orthopedic surgeon.

From this study it is clear that a pillow splint, if properly applied and supervised, is an adequate treatment for congenital subluxation in early infancy. It must remain on until abduction is fully obtained and the roentgenographic features return to normal. Once the splint is applied, the child should be examined every six weeks to be sure that the splint is being used correctly. The second set of x-rays is not taken until three months after treatment. After correction is obtained in cases of subluxation, the patient should be followed for at least twelve months and, ideally, until cessation of growth. Not infrequently, we thought correction was obtained; then many months later signs of subluxation became evident again. In such a case one should not hesitate to start over with any treatment which may be necessary.

---

Doctor, I've Got . . .

As I lay sleeping snug last night
A man appeared to me;
He said, "I suffer severe frost bite,
And chondromalacia, knee.

"Arteriosclerosis obliterans
Has luckily passed me by,
And my myositis ossificans
Would scarcely trouble a fly.

"But pruritus ani plagues me by day,
With superimposed erythema;
At night, wherever my legs I lay,
I'm troubled with pedal edema.

"Hypertension essential is what I've got,
And a mild cerebral thrombosis;
With partial aphasia, an aching gut,
And a scatter of keratosis.

"I've gout, neuritis, anxiety state,
And a touch of schizophrenia,
In remission, and complicated of late
By acute and pernicious anemia.

"Oh, I am an excellent candidate
For an early and careful trephining,
Or soon I'll be lying in lonely state
Where the gentle woodbine's twining."

I was wringing my hands for the wretched bloke
When he suddenly vanished in air;
And mercifully, I then awoke
From the night wind blowing my hair.

Pseudomembranous Enterocolitis

A Comparison with Staphylococcal Colitis

J. H. STRICKLER, M.D.
CARL O. RICE, M.D., Ph.D.
Minneapolis, Minnesota

PSEUDOMEMBRANOUS ENTEROCOLITIS is a rapidly and highly lethal disease of unknown or variable etiology. Most of the literature credits Finney with the first description of this disease in 1893. However, Bloomfield[2] records a description by Bilroth in 1867.

Pathologic Characteristics

Mucosal necrosis is considered by Durrani[6] as an indispensable and outstanding morphologic feature. The necrosis is usually limited to the mucosa[11] and often involves only the tips of villi[19] or the mucosal folds.[11] Venules and capillaries, but never arterioles, are blocked by fibrinous thrombi.[11,19] The pseudomembrane resembles diphtheritic type and consists of necrotic mucous membrane, fibrin and inflammatory debris.[11,18,19] Kay[11] prefers to name this disease "acute necrotizing (pseudomembranous) enterocolitis." The distribution of the lesions classified from the largest series[20] involved small bowel in 44, small bowel and colon in 24, and colon alone in 12.

Clinical Features

Onset

Onset is sudden and is associated with shock and collapse.[6,8,14,20] In this respect it resembles the abrupt onset of Asiatic cholera.[5] Most of the larger series reported in the literature are from autopsy material.[2,4,6,14,19,20] Of 107 cases studied by Pettit,[20] only six lived 48 hours after shock was noted; 50 per cent died within 12 hours. Kay[11] found the same rapid deterioration in a 16-case study. Dixon[5] reported 91 per cent mortality in 23 cases. Frank peritonitis existed in 12 of the 21 deaths, and three showed a gangrenous segment of bowel. Pettit[20] found evidence of peritonitis in 63 per cent of his 107 autopsies. Eiseman[7] cited a 74 per cent mortality on the basis of three recently published reports.

Nearly all of the cases appear following surgery on the intestinal tract[5,18,19,20] and most commonly after a gastrectomy;[11] however, a few cases are described in the debilitated or chronically ill patient.[14] In one report[11] half of the nonoperated cases appeared in patients with cardiac problems. The interval between operation and onset of the pseudomembranous enterocolitis is very short, the highest frequency occurring the second or third day.[11,18,20]

Diarrhea

Though not a prominent feature, diarrhea,[5,6,11,20] when it does appear, is usually small in volume and of rice-water character.[5] Van Prohaska,[21] however, considers severe diarrhea to be an important sign. In view of the preponderance of opinion against this observation, it is quite likely that he is observing a different entity — namely, staphylococcic enteritis.

Causative Factors

Shock

Most authors[5,6,11,14,18] do not consider shock to be a causative factor, but rather a signal of the onset, i.e., a consequence of the disease. However, in the review of only one paper[19] is antecedent shock assigned an etiologic role in pseudomembranous enterocolitis by virtue of altered vasomotor mechanisms.

Impaired Circulation

Chronic arterial insufficiency is suggested as a predisposing condition, setting the stage for development of necrotizing lesions of the bowel mucosa. Marston[15] suggested that preexisting ischemia of the bowel of elderly persons sets the stage for the development of a group of obscure bowel lesions with necrosis, whenever a state of shock develops. Pseudomembranous enterocolitis, staphylococcic enteritis, infarction of bowel, acute necrotizing enterocolitis, and acute hemorrhagic necrosis of the gastrointestinal tract were all regarded by this author as variants of the same problem.

Wilson[27] considers acute hemorrhagic enterocolitis in the chronically ill to be due to chronic congestion and cellular anoxia of the bowel mucosa, and he further believes it to be a separate entity from pseudomembranous enterocolitis.

In the cases of mesenteric arterial obstruction reported by Shaw,[24] a malabsorption syndrome developed — possibly secondary to insufficient oxygen supply. The bowel, however, appeared to have no gross lesion.

Laufman[13] experimentally produced a gradual occlusion of mesenteric vessels in dogs; but in spite of this he observed only a low-grade enteritis and some small subserosal thrombi. The observations of Wilson,[27] Shaw[24] and Laufman[13] are, therefore, probably unrelated to pseudomembranous enterocolitis.

Antibiotics

The broad-spectrum antibiotics have been implicated by some authors[2,10,18,23,25] and absolved by others.[6,8,11,20] Johnston[10] considered a causal relation to exist, but all 14 of his cases recovered, casting doubt upon the accuracy of this classification. Valberg[25] found no staphylococci or other pathogens, even though all his cases had received antibiotics, and, therefore, postulated some direct deleterious effects of antibiotics on the mucous membrane. The most convincing evidence against the theory that antibiotics have a causative role is found in the Mayo Clinic Autopsy Series of 107 cases reported by Pettit,[20] who found an equal number of postoperative pseudomembranous enterocolitis cases in the pre and in the postantibiotic years.

Staphylococcus

Micrococcus pyogenes (staph) enterocolitis is known to produce a pseudomembrane as well as other features resembling pseudomembranous enterocolitis. However, considerable debate exists whether the conditions are the same or merely similar. The most convincing argument favoring staphylococcic etiology is presented in the study of van Prohaska and associates,[21,22,26] who believe that the remarkable response of pseudomembranous enterocolitis to corticotropin and erythromycin is evidence that staphylococcus enterotoxin causes the shock phase of the disease. This hypothesis was supported by the production of lethal enterocolitis by administration of staphylococcic enterotoxin to chinchillas.[26] Pearce and Dineen[18] concluded that broad-spectrum antibiotics resulted in an overgrowth of staph in the gastrointestinal tract and that the staphylococcus caused pseudomembranous enterocolitis. It is very significant that their series included nonfatal cases of diarrhea with stool cultures of pure staph, therefore resting upon the dubious thesis that staphylococcic enteritis and pseudomembranous enterocolitis are the same disease. Eiseman[7] made this same assumption in reporting treatment by fecal enemata. All four of his cases had severe diarrhea: a feature not at all constant or even prominent in pseudomembranous enterocolitis. The predominant opinion obtained by review of the literature does not favor the theory that the staphylococcus (micrococcus pyogenes) causes pseudomembranous colitis. Many authors[4,8,11,14,25] have failed to find positive staphylococcic stool cultures in this disease.

Clinical Management

Treatment of pseudomembranous enterocolitis involves early recognition and rapid, forceful supportive therapy. Pearce and Dineen[18] state that the survivors receive supportive treatment and erythromycin an average of 5.7 hours after onset. Cortisone[10,11,16,18] or corticotropin[3,21,22,25] or norepinephrine has also been recommended in shock phase.[10,11] The recommendation for use of norepinephrine should be carefully reconsidered, since on the basis of the pathologic process it is probably contraindicated, for more spasm in the arterioles adjacent to the thrombotic mucosal capillaries might be expected to advance the necrotic process.

Surgery

More attention should be directed toward determination of the presence of peritonitis secondary to perforation or necrosis of the bowel wall having advanced to the stage of bacterial migration so that extirpative surgery can be employed as a lifesaving attempt.

Although pseudomembranous (necrotizing) enterocolitis has an extremely high mortality, and despite the frequent autopsy findings of perforation and peritonitis, the literature contains very few suggestions that direct surgical approach may have value in any phase or stage of the problem. In a discussion of the paper by van Prohaska,[21] W. C. Bartlett described operating on a case 24 hours after onset of shock. Gangrene and multiple perforations of the entire small bowel and right colon were treated by resection and anastomosis of the upper jejunum to transverse colon. His patient lived eight months.

Kay[11] advised operation to differentiate between high obstruction after gastrectomy and pseudomembranous enterocolitis; however, he did not suggest extirpative therapy of the enterocolitis. Killingback[12] advised wide resection of the diseased bowel. After initial attempts in earlier series had failed because of leakage at all anastomoses, he recommended a proximal and distal colostomy and later closure. Four survivors were reported from seven cases, all of whom were operated upon.

Differential Diagnosis

Staphylococcus

Staphylococcus (micrococcus pyogenes) will not grow well on routine eosin methylene blue-culture media, due to overgrowth of other bacteria. Therefore, stool cultures must be made on blood agar or phenylethyl alcohol media.[16] However, in later studies,[4,25] particular attention has been properly given to this point.

Pseudomembrane

The pseudomembrane may actually occur in a variety of unrelated conditions and probably represents a means of the bowel reacting to certain toxic stimuli.[2] Altmeiter[1] found that of 155 patients with staphylococcic enteritis, only nine had autopsy-proven pseudomembranous enterocolitis. The Mayo Clinic series of Dearing and Bagenstoss[4] failed to relate staphylococcic infection and pseudomembranous enterocolitis with any regularity. They also noted that staphylococcic enteritis usually responded to proper antibiotic therapy, whereas pseudomembranous enterocolitis has always been rare and did not respond to treatment whether staph was present or not. Fowler[9] found staphylococcic enteritis was not associated with a pseudomembrane and considers it important to differentiate between staphylococcic enterocolitis and pseudomembranous enterocolitis. Penner and Bernheim[19] believe that infection follows onset of pseudomembranous enterocolitis, since infection is not present in the earlier lesion.

Dr. Edward S. Judd, commenting on Markley's paper,[14] stated: "A rather sharp distinction can be made between modern enteritis due to staphylococcus aureus and the old well known pseudomembrane disease which the elder Finney described so beautifully before the turn of the century."

Cl Welchii

Cl welchii has been reported as a causative agent in necrotizing colitis,[12,17] a condition somewhat similar to pseudomembranous enterocolitis. One author named the condition enteritis necroticans and considers it the "Darmbrand" of North Germany and the same as "Struck" in sheep, a disease condition caused by Clostridium welchii and characterized by necrosis of bowel mucous membrane. Killingback[12] considers necrotizing colitis to be a separate entity from pseudomembranous enterocolitis.

Since pseudomembranous enterocolitis is a disease of unknown etiology, and staphylococcic enteritis is a specific disease entity, certain important differences may be enumerated which separate the two diseases.

Staph Enteritis

1. Usually follows broad-spectrum antibiotic therapy.
2. Profuse diarrhea.
3. Response to proper antibiotic (Erythromycin) and supportive therapy.
4. Generally recovers.
5. Pseudomembrane may or may not be present and is usually absent.
6. Diagnosis may be made by stool smears before culture identifies micrococcus pyogenes.

Pseudomembranous (Necrotizing) Enterocolitis

1. Commonly not related to antibiotic therapy — present as frequently before as after antibiotic era.
2. Minimal to no diarrhea.
3. Severe shock — sudden onset — collapse. Shock being a result and not cause of.
4. Failure to respond to therapy. Extremely high mortality.
5. Commonly follows surgery (usually gastric or colon).
6. May on occasion follow myocardial infarction.
7. Pseudomembrane may or may not contain staphylococcus (special cultures included).
8. Mucosal necrosis is an essential feature.
9. Cause unknown — no specific etiologic agent identified.

Additional Observations

If pseudomembranous enterocolitis is due to Staphylococcus (micrococcus pyogenes) in the absence of coliform bacteria, such as after antibiotic preparation, why should many cases involve the small bowel and even the stomach, where colon bacteria are not found, at least in any quantity?

The literature contains reports of enteritis of weeks' duration and of prolonged diarrhea. It seems evident that many varieties of enteritis have been classified as pseudomembranous enterocolitis without attention to the most specific criteria of pseudomembranous enterocolitis — the mucosal necrosis.

Postoperative Pseudomembranous Enterocolitis

The patient was a 68-year-old woman with peptic ulcer symptoms of one year's duration. Strict medical management produced no relief. Evening vomiting of increasing volume developed over a three-week period. A bleeding episode then appeared, requiring three transfusions. Re-x-ray revealed a 1 cm. diameter posterior duodenal bulb ulcer with some pyloric obstruction.

Past history involved only a cholecystectomy for stones 11 years before and a few years of mild diabetes, well controlled on two Orinase tablets daily.

Gastrectomy for Ulcer

On February 3, 1964, a two-thirds (197 grams) gastrectomy was performed on a moderately hypertrophic stomach. A Bilroth II reconstruction was done with the duodenal stump closed against the pancreas.

Postoperative Sequelae

The immediate operative period was entirely uneventful. However, at 12 hours post operative, flatus and a small amount (a few cc.) of liquid stool were passed. Whereas this was rather remarkable, it was unimpressive at the time and no culture or smear was taken. A similar very small liquid-stool passage occurred twice more in the ensuing 18 hours. Twenty-four hours after surgery the temperature rose to 102 and 103 degrees, with a slightly tender abdomen. The serum amylase was normal. Intravenous chloromycetin was started empirically at 1.5 grams per day. Generalized abdominal tenderness of a moderate degree developed. Forty-eight hours after operation blood pressure dropped to 80 systolic. Serum sodium was 120 and chloride 81, in spite of the patient's having received polyionic maintenance solution. Urine output ceased.

She was given 250 cc. of 3-per cent sodium chloride. Pressure rose to normal. Urine began to flow and she was given another 250 cc. of the same solution. Her condition stabilized, but with persistence of abdominal pain, some rigidity and rebound. Ten hours later shock again appeared with no electrolyte disturbance. Two units of plasma were rapidly given, also 500 mg. of hydrocortisone intravenously. The blood pressure returned to the normal 120 and remained stable. She was then given two more units of plasma, and additional diagnostic efforts were undertaken.

The abdomen was tapped with a 190-polyethylene tube threaded through a 15-gauge needle. Foul-smelling gas was obtained as soon as the stylet was removed from the needle. On the possibility of having entered the colon, the abdomen was tapped in another area with the same result of foul odor. A few cc. of brownish peritoneal fluid were obtained, and a gram stain revealed staphylococci with a few gram-negative rods.

Exploratory Laparotomy

On February 6, 1964, the third postoperative day, exploratory laparotomy was performed on the diagnosis of peritonitis, cause undetermined. The first view was a gangrenous transverse colon. Thereupon, the mid-colic vessels were carefully inspected and found to pulsate as far as the more terminal branches. Further exploration revealed patchy areas of gangrenous necrosis in the right and left colon. There was no involvement of the small bowel or stomach pouch and minimal if any involvement of the rectosigmoid a few inches above the peritoneal reflection. One or two hundred cc. of watery brownish fluid were in the peritoneal cavity. Foul odor was evident, and it was obvious that the colon was in an advanced stage of patchy necrosis with nearly total involvement of the transverse colon. No obvious areas of free perforation with fecal leakage were evident. The necrotic colon wall was, therefore, still sufficiently intact to retain the content of the lumen from free leakage. There was no appreciable distention of bowel. The clinical diagnosis of pseudomembranous enterocolitis was verified by the pathologist upon removal of the bowel.

The colon was removed from terminal ileum to rectosigmoid. A terminal ileostomy was made and a distal colostomy directly above the pubis achieved a mucous fistula of the distal segment. Vital signs remained surprisingly stable. The patient received three units of plasma on the operating table.

Pathologic Examination

The intestine was 90 cm. long with a total fluid content of 1500 cc. containing shreds of tissue compatible with mucosa. After cleaning the mucosal surface, one fourth of it appeared to be denuded. This included several wide areas in the cecum, transverse colon, and descending colon.

The microscopic examination showed dense inflammatory reaction with the muscle wall intact in most areas; section of the loose membrane revealed what appeared to be necrotic mucosa with many bacteria, the majority being of coccal form.

Diagnosis: "Pseudomembranous enterocolitis or staphylococcal colitis."

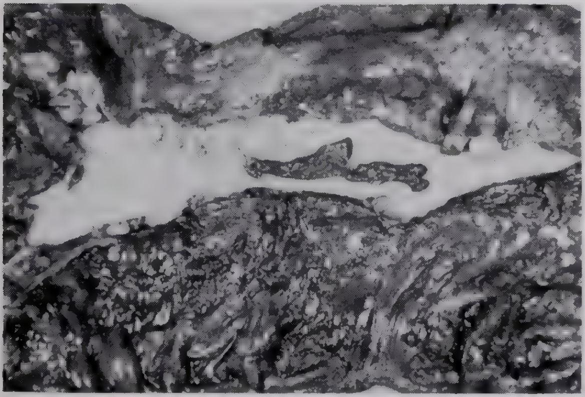

Fig. 1 — Photograph of gross specimen

Bacteriologic Examination: "Abdominal fluid from preoperative diagnostic paracentesis and from bowel wall reveal gram-positive cocci and a few gram-negative rods. Hemolytic coagulase positive staph aureus and pseudomonas aerugenosa on culture. The staph is sensitive to all tested antibiotics with the exception of penicillin, gantrisin, and polymyxin B."

Convalescence

Unipen was given parenterally, two grams per day, and also in divided doses into the mucous fistula of the distal sigmoid. By three weeks postoperative, pseudomonas was the only positive culture from both abdominal wound and rectal stump. Therefore the patient was put on Coly-Mycin. In about another week, the vaginal and perianal areas were obviously infected with a fungus. Culture revealed Candida albicans. This was treated locally with Fungisone lotion. The Coly-Mycin was discontinued at two weeks. The antifungal treatment continued for an additional two-week period, followed by complete clinical clearance. Finally, the bacterial flora of the mucous fistula of the distal colon returned to essentially normal distribution of bacteria except for a modest quantity of fungus. Suppositories of Mycostatin were inserted daily into the distal colon. The ileostomy output was of mushy stools with no abnormal quantity.

Smoldering Colitis

A smoldering colitis remained in the distal stump between the level of the peritoneal reflection and the mucous fistula, a distance of approximately six to eight inches. This was examined frequently by sigmoidoscope both through the mucous fistula and the anus. The rectal region remained entirely normal. The distal colon was treated four times daily with Medcort enemas, a solution of methyl cellulose and cortisone. Liver function survey failed to reveal any abnormality. Intravenous urography showed normal function and contour of the urinary collecting system. Urinalysis revealed only a few pus cells.

Pseudomonas

The patient was discharged on March 27, 1964,

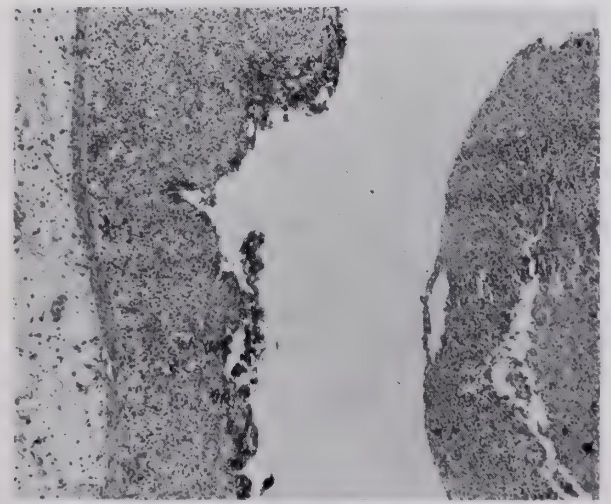

Fig. 2 — Representative microscopic sections

approximately eight weeks after her gastrectomy.

She was readmitted on April 4, 1964, because of return of low-grade fever, disorientation, and marked anorexia. On the thesis that she might have a residual intra-abdominal undiscovered abscess, she was treated with chloromycetin, 1.5 grams daily, and Unipen, 1.5 grams daily, for 10 days. Her temperature subsided within two days. As the mucous fistula revealed slight redness of the mucous membrane, cortisone enemas were reinstituted, and at the end of 10 days the bowel appeared entirely normal, with the usual dry sticky mucous. Urinalysis revealed no pus cells, but a culture showed 100,000 colonies of pseudomonas per cc. This was treated with streptomycin. Intravenous pyelogram showed no areas of statis, stones, or other abnormalities. She was discharged on Mandelamine, ½ gram q.i.d. to be continued indefinitely. Much improved the patient was again discharged on April 27, 1964.

Follow-up Observations

One month later proctoscopy was entirely negative from both directions, hemoglobin normal, white count 8250, and a weight gain of two pounds. On August 3, four months after the gastrectomy, six weeks after final discharge, the patient suddenly expired. At autopsy there were no abscesses within the abdomen or liver. The kidneys showed many irregular abscesses and papillary necrosis. Smears revealed pus cells and gram-negative rods. Both the small and the residual colon appeared normal. The lungs showed minimal pulmonary edema and congestion. The presumptive diagnosis was that of gram-negative septicemia with sudden shock. In retrospection it was found that in another location a urinalysis two weeks prior to death revealed a packed field of pus cells. This finding was never treated.

Clinical Conclusion

Early intensive and broad antibiotic coverage seemed essential but brought on a series of successive problems: the overgrowth of pseudomonas and the Candida-albicans problem. Whereas erythromycin is ordinarily considered the antibiotic of choice, there was obvious and massive peritoneal soilage by migration of bacteria through the gangrenous bowel wall; and upon the anticipation of abscess development in the face of infection that was not purely staphylococcal, the more broad coverage was elected.

Since small bowel and distal sigmoid appeared to be free of the disorder, and since nearly the entire colon needed sacrifice because of irreversible necrotic changes, an ileostomy and separate distal colon mucous fistula were performed in the anticipation of later re-establishment of bowel continuity by an ileosigmoidostomy. From the standpoint of bowel recovery that actually occurred, this could have been achieved.

The diagnostic abdominal tap removed any question of the urgency of reoperation three days after the gastrectomy by obtaining foul smelling gas from the free peritoneal cavity and a smear of fluid containing both cocci and gram-negative rods.

The employment of mucous fistula affords an excellent means of both treatment and inspection of the partially involved distal colon.

In view of the highly fatal outcome of this fulminating type of pseudomembranous enterocolitis, some future cases may be permanently salvaged by early resection of obviously necrotic bowel with a plan for restoration at a later date. If at laparotomy gangrenous areas are not present, treatment of choice should probably be continuation of medical management.

The Amputation Site in the Lower Extremity

Regard for the Vascular Efficiency

HENRY C. WESSMAN, M.S., R.P.T.*
Minneapolis, Minnesota

THE EFFICACY of the circulation is the important consideration in the selection of a site for amputation. After the amputation has been performed, the circulation in the stump is subject to the same problems as that of the other extremity.

When amputation is required for trauma, Marmor and Sollars[1] recommend that as much as possible of the extremity be saved in the initial surgery, and that any revision be left for a subsequent procedure.

The greatest number of amputations are performed for some type of peripheral vascular disease,[2] and approximately 70 per cent[3,4] are in elderly patients. In the present day of reconstructive vascular surgery every effort should be made to salvage the entire limb; however, if this is not possible, determination of the proper amputation site should be given consideration. In addition to providing an adequate stump for use of a prosthesis, the surgeon must be aware of the rehabilitative facilities which are available to his patient.[5]

Criteria for Determining the Amputation Site

In doing an amputation, it is hoped that the stump can have a maximal functional length with the best possible skin covering, and hence possess the best odds for fitting the prosthesis and successful rehabilitation.

Below the Knee Amputation

Adequate collateral circulation is most frequently associated with a slow onset of the disease process or a more distally lodged embolus if one is present.[6] The criteria for doing an amputation below the knee[7] are indicated in Table 1.

This investigation was supported by Research and Training Grant Number 2 of the Vocational Rehabilitation Administration.

*Department of Physical Medicine and Rehabilitation, University of Minnesota Hospitals.

TABLE 1

Criteria for Below the Knee Amputation[7]

Slow Onset of Disease Process
Palpable Femoral Pulse
Functional Knee
Unaffected Skin to Mid-Leg
Good Bleeding in Skin and Muscle at Amputation Site
Hope of Rehabilitation

Above the Knee Amputation

Sudden occlusion together with the lack of femoral pulsation usually indicates that the collateral circulation has not had time to develop, and it has been observed[6] that this condition exists frequently in patients with a cardiac lesion or low blood pressure insufficient to force its way through the collaterals. At the time of surgical operation, if the muscle is pinkish gray, bleeds poorly, and does not contract, surgery must be performed at a higher level.[4] Other criteria[7] are indicated in Table 2.

TABLE 2

Criteria for Above the Knee Amputation[7]

Sudden Onset of Arterial Occlusion With:
- Weak or Absent Femoral Pulse
- Low Skin Temperature
- High Venous Filling Time
- Evidence of Ischemia
- Poor Bleeding at Amputation Site

Embolic Occlusion and Gangrene

Prosthesis

If the patient can use an artificial limb without overexertion, a prosthesis is indicated. There have been some instances[8] in which the use of a prosthetic device has provided an improvement in circulation. If the proper criteria for doing an amputation are not observed, there may be a breakdown of the skin, edema, and a variety of undesirable complications.

Measuring the Efficiency of the Circulation

Each method of measuring the circulation gives a different evaluation; no one of the following methods is adequate for sole evaluation of the peripheral blood flow.

The Oscillometer

The oscillometer[9] measures the pulsatile change of volume in all the tissues under the cuff with each heart beat. It is easily used in a ward and does not require a basal condition.

Skin Thermometry

Skin thermometry using contact thermocouples taped to the skin is a simple method of assessing the ability of the sympathetic system to respond to vasodilating stimuli. The thermocouples are usually attached to the big and little toes and the sole and dorsum of the foot. Skin thermometry is not a convenient clinical tool, however, because it requires a constant-temperature room in order to provide an accurate reading.

Arteriography

The injection of contrast media into the femoral artery and the observation of the vascular outline are valuable in detecting evidence of collateral circulation.[10] This is the best method of graphically portraying the peripheral circulation.

*Plethysmography**

Venous occlusion plethysmography is performed by enclosing the extremity in an air or watertight box, occluding the venous return, and measuring the volume change in the box which corresponds to the arterial inflow of blood. An erroneous plethysmogram will be obtained if the venous return is not completely arrested. The patient must be in a basal condition and in a constant-temperature room. Plethysmography provides an excellent picture of the sympathetic response; it is the best method of assessing a total arterial inflow in any given segment.

Interpretation

Some of the composite circulatory indices that may be expected in the lower extremity with a room temperature of 26 ± .5 degrees C. during rest and indirect heat are indicated in Table 3.[9,11] The use of indirect heat serves to demonstrate the ability of the sympathetic system to respond to stimuli.

---

*See Test Your Word Score Page 943.

Plethysmography Values

The plethysmographic values during the resting state are self-explanatory, and when values fall below these figures the arterial inflow is considered to be deficient. A minimal satisfactory sympathetic response of the circulation with indirect heating would be an approximate increase of two times the control value in the calf and three times the control value in the foot.

Oscillometric Indices

The oscillometric indices are based on the resting state only; change in the oscillometric index is not of stable diagnostic value following indirect heat. When the oscillometric index falls below "trace" at the instep, the circulation is considered to be inadequate for wound healing in the foot.[9]

Skin Temperature

Skin-temperature increases following indirect heat should go beyond 32 degrees C. in both the foot and the calf to indicate minimal sympathetic response of the circulation. Increase in temperature will generally exceed this figure by two to four degrees C. in both the foot and the calf.

In all instances indicated in Table 3 the smaller values are minimal, and it must be remembered that the values will vary in individuals and also as influenced by ambient temperature. These minimal values are at a level below which some form of surgery would probably be indicated if found in more than one of the methods which have been discussed.

Summary

Peripheral circulation is the primary consideration of amputation site. If amputation is performed, the circulation in the stump is subject to the same problems as that in the other extremities. The site of amputation may be selected in different ways depending

TABLE 3

on whether the amputation is traumatically caused or is a result of peripheral vascular disease.

Oscillometry, skin thermometry, arteriography and venous-occlusion plethysmography are all methods of assessing the efficacy of the peripheral circulation. Each tells a different part of the story. Of the four, oscillometry is the most easily used clinically. Arteriography is of particular value in assessing collateral circulation. Venous-occlusion plethysmography is the best method available for determining the total inflow of blood into a given area.

IT'S THE LAW

Hospital and Doctors not Liable in Patient's Death from Heart Disease

The administrator of the estate of a deceased patient was not entitled, in a suit against a hospital and two doctors, to recover damages for her death from heart disease, where there was no evidence that the negligence, if any, on the part of the hospital or the doctors was the cause of her death, the Court of Appeals of Kentucky ruled.

About a year before her death, the patient had been treated and hospitalized for pains in her arm, shoulder, and chest, and for shortness of breath. When her trouble recurred, she consulted a doctor who referred her to the hospital. That day she was seen by one of the two doctors and two days later by the second one. The patient died the morning after she had seen the second doctor.

An autopsy disclosed a hardening of the arteries of the heart, a necrosis of a heart muscle, and an apparently severe hardening of one of the arteries to the brain.

The evidence of negligence was unconvincing, the court said. The doctor who treated the patient for her heart trouble a year before her death testified that there was no one sign that could be associated with heart disease and nothing else. If it was assumed that the evidence established negligence, there was still no evidence that the negligence was the proximate cause of the patient's death.

Two doctors gave testimony critical of the treatment the patient received in the face of her symptoms and stated the opinion that she might have survived if she had received proper treatment for her condition. However, both witnesses admitted that there was no way they could conclude that she would have survived if she had had the treatment they recommended and neither would say that her failure to get that treatment caused her death.

The Vision Interference Indicator*

Device
for
Teaching
Tonometry

LAWRENCE L. GARNER, M.D., F.A.C.S.**
Milwaukee, Wisconsin
JAMES E. FULGHUM, JR., B.B.A.†
Washington, D. C.

UNTIL RECENTLY, the Schiotz tonometer, which measures the intraocular pressure, was primarily used by ophthalmologists. As the prevention of blindness from glaucoma is dependent upon early recognition and therapy many medical schools now include tonometry in the teaching curriculum for the undergraduate. The internist and general practitioner should screen for glaucoma.

In the case of open-angle glaucoma, by the time the patient is aware of symptoms, irreversible damage to the optic nerve may be found on the first visit. The majority of open-angle glaucoma patients have minimal or no complaints relating to their glaucoma and usually present themselves only for a change of glasses. Ophthalmologists routinely perform tonometry as a part of the eye examination. The table shows what the tonometry screening tests will yield as compared with other screening tests that are considered routine.

Development of the First Mannequin

Students have been trained in the technique of tonometry by using a test block and then by measuring the intraocular pressure in the eye of another student. To facilitate training and obviate apprehension, however, a mannequin was developed by the Neurological and Sensory Disease Service

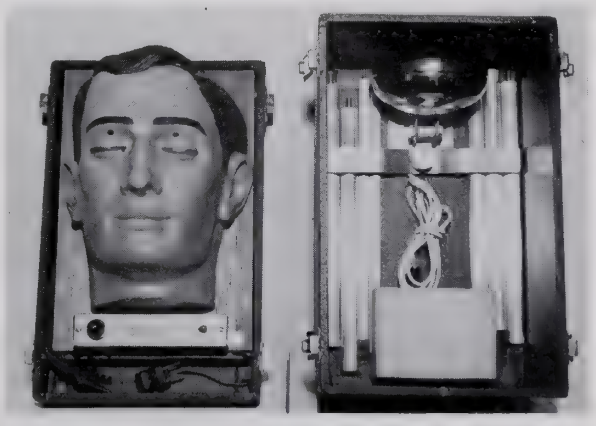

Fig. 1 — Take-apart assembly dismounted and housed in cover of carrying case. The portable case measures 14x9x9 inches and weighs approximately 17 pounds complete. Assembly is easily accomplished within a few minutes. The take-apart assembly may be eliminated in areas having a drop light, thus permitting a sealed-beam lamp with directing cone to serve as the source of light.

†Public Health Advisor, Neurological and Sensory Disease Service Program, Public Health Service, U. S. Department of Health, Education and Welfare.

TABLE I

Disease and Population		Screening Test	Confirmed Diagnosis Per 1,000 Screened	%
Glaucoma:	General population over age 40	Tonometry	20 in 1,000	2.0
Diabetes:	General population	Blood tests	8 in 1,000	0.8
Cancer:	Females over age 25	Pap smear	4 in 1,000	0.4
Tuberculosis:	Adults	Chest X ray	1 in 1,000	0.1

The estimates noted in this table were compiled by the Neurological and Sensory Disease Service Program, Division of Chronic Diseases, Public Health Service, from several sources.

Program of the Public Health Service. This mannequin, which was tested at Marquette University Medical School, has realistic elastic lids with interchangeable eyes that have an elevated tension in one eye and normal tension in the other. This became a practical and popular training device and was subsequently offered to other medical schools.

Development of the Vision Interference Indicator

To ensure accurate readings the patient's eyes must remain still during the test; therefore he is asked to look at his thumb held overhead, thus maintaining the eyes in the straight-forward position as the tonometer is brought from the side and placed on the cornea of the eye being tested. Since the contralateral eye continues to regard the fixation area, no movement should be noted in the eye being tested.

The most common error in technique is related to inadvertent covering of the fixing eye of the patient by the hand or head of the person performing the test. This occurs as a result of improper placement of the hand holding the tonometer or the hand spreading the lids for exposure of the eye for the tonometer. To eliminate these common errors in technique during training we modified the apparatus to include photoelectric cells in the mannequin's lids with a beam of light that triggers a buzzer if blocked over both eyes at the same time (Figure 1). The second most common error noted is the improper separation of the eyelids which should be held open with the index finger and thumb against the orbital bone and not against the eyeball. This technique will eliminate a false positive test that would result if the finger of the examiner pressed on the globe.

"The Vision Interference Indicator" mannequin is an improved means of teaching tonometry to the physician or student and is available, along with the exhibit "Conserve Vision-Detect Glaucoma," for national, state, and regional medical meetings.

Severe Anemia

as a Cause of

Heart Failure in Infancy*

RICHARD H. SEARL, M.D.**
ROBERT C. SPECKHALS, M.D.**
Faribault, Minnesota

ALTHOUGH IRON deficiency anemia is reported to occur in up to 30% of infants,[1] it is unusual to observe hemoglobin concentrations below 5 grams per 100 milliliters of blood. This case report illustrates an unusually severe anemia which resulted in myocardial decompensation.

Case Report

A one-year-old white girl was admitted to Rice County District One Hospital because of listlessness and pallor. She had been irritable and fussy and had eaten poorly for several weeks. Since birth she had been fed only milk and mashed potatoes.

The patient, the fourth child of a 23-year-old woman, was delivered by cesarian section at 45 weeks normal gestation and weighed 4 kilograms at birth. At six weeks of age her weight was 5.5 kilograms and her hemoglobin 14.4 grams per 100 milliliters of blood. At 14 weeks of age she weighed 7.9 kilograms. The mother was not anemic, and there was no family history of hematological diseases. The child was not seen again by a physician until the date of admission, a lapse of over eight months.

Physical Findings

On admission physical examination revealed a well developed, extremely pale and listless child weighing 9.2 kilograms. The cardiac rate was 100 per minute, the respiration rate 36 per minute and the rectal temperature 100° F. There was no cervical venous distention. The pulmonary fields were clear. While cardiac rhythm was regular, a grade III/VI blowing holosystolic murmur was heard along the left sternal border, extending into the axilla. Palpation of the precordium revealed a hyperactive heart but no right or left ventricular heave. The liver and spleen were not palpable. Good pulsations were present over both femoral arteries. No peripheral edema was present. Neurological examination revealed marked generalized muscular weakness.

Laboratory Findings

The hemoglobin concentration was estimated to be 1.6 grams per 100 milliliters of blood; the hematocrit was 7.0% and the RBC 1.5 million. The peripheral blood smear showed hypochromasia and microcytosis (Figure 1). The mean corpuscular volume was 46.6 cubic microns; the mean corpuscular hemoglobin was 10.6 micro micrograms, and the mean corpuscular hemoglobin concentration was 23%. An electrocardiogram was normal. A routine urinalysis was negative for albumin, glucose and formed elements. Stools for occult blood and a direct Coombs test were negative. The total blood leukocytes and differential counts were normal.

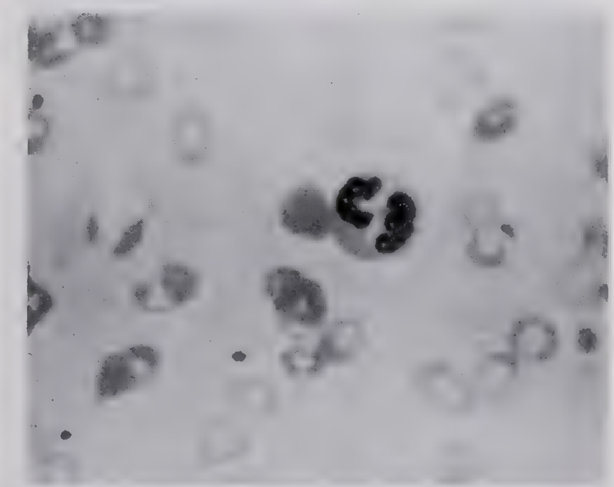

Fig. 1 — Initial peripheral blood smear. Hemoglobin concentration was 1.6 gm./100 ml. of blood and the hematocrit was 7.0%. There is marked microcytosis and hypochromasia. (Wright's stain x 1,000).

---

*Read before the annual meeting of the Southern Minnesota Medical Association, September 10, 1965, Sheraton-Ritz Hotel, Minneapolis, Minnesota.

**Faribault Clinic.

Therapy

Oral iron therapy was begun with ferrous sulfate (60 mg. elemental iron daily). The following day, twenty-eight hours after admission, the patient suddenly developed myocardial decompensation manifested by a cardiac rate of 160 per minute, respirations of 72 per minute, and liver edge palpable 8 cm. below the right costal margin. A thoracic roentgenogram (Figure 2-a) revealed cardiac enlargement and pulmonary vascular congestion. The child was placed in an oxygen tent, digitalized and given a mercurial diuretic. A transfusion of 90 milliliters of packed red cells was administered 18 hours later. At the end of 24 hours all signs of cardiac decompensation had disappeared and no further blood transfusions were given. A thoracic roentgenogram five days later showed clearing of the pulmonary vascular congestion (Figure 2-b).

The response to therapy is summarized in Figure 3. The reticulocyte count increased rapidly following administration of oral iron and was accompanied by a progressive rise in hemoglobin concentration. A temporary depression of the reticulocyte count occurred following the transfusion of packed red cells.

The child continued to show improvement on adequate diet and oral iron therapy. On the seventh hospital day when the hemoglobin concentration was 8.3 grams per 100 milliliters of blood, and the hematocrit was 26.5%, the patient was discharged. Digitalis was discontinued on the 23rd day. The cardiac murmur disappeared by the 42nd day of therapy. At eighteen months of age the child had a normal hemoglobin concentration, no cardiac murmur, and a normal thoracic roentgenogram. At this time iron therapy was discontinued.

Discussion

Although serum iron determinations were not obtained, the striking response to oral iron therapy indicated by the reticulocytosis and by the increase in blood hemoglobin concentration is confirmatory evidence of iron deficiency anemia.

The effects of anemia upon the cardiovascular system and the occurrence of congestive cardiac failure have been well documented.[2,3] Cardiac manifestations seldom occur with hemoglobin concentrations above 7.0 grams per 100 milliliters of blood. Organic cardiac disease must always be considered in anemic patients who develop congestive myocardial failure, even when the hemoglobin concentration is below this level. In the case reported, treatment of the anemia resulted in a return to normal of the cardiac status.

Causes of Iron Deficiency

The four important causes of iron deficiency in infancy[1] are: (1) deficient iron stores at birth; (2) rapid growth rate especially of small or premature infants; (3) inadequate intake of iron; and (4) blood loss. Maternal iron deficiency is important only when the mother has a severe hypochromic anemia (hemoglobin concentration less than 7 grams per 100 milliliters of blood).[4] As small (less than 3000-gram) infants have less total iron at birth than large infants, their rapid growth rate predisposes them to hypochromic anemia. The influence of diet has been recognized for many years.

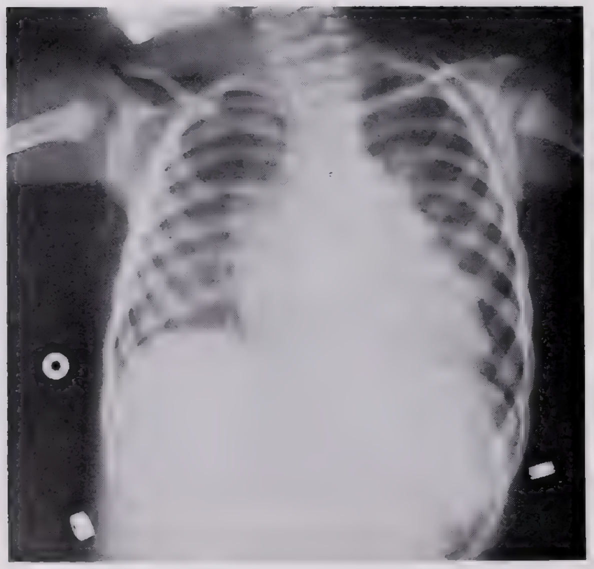

Fig. 2-a — Initial chest x-ray showing generalized cardiomegaly and pulmonary vascular congestion.

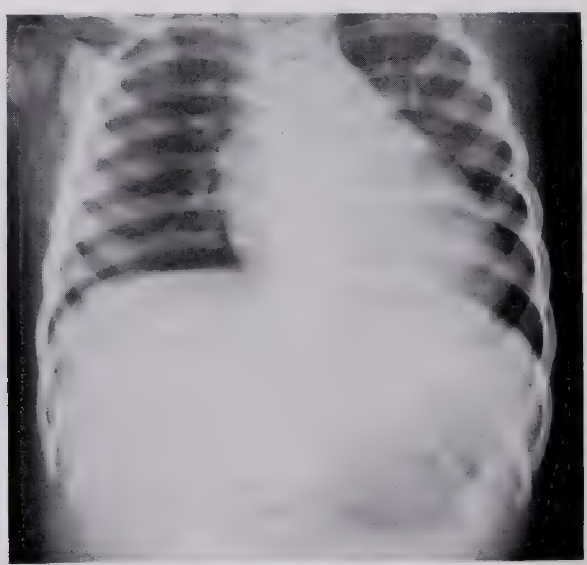

Fig. 2-b — Chest x-ray five days later showing clearing of the pulmonary congestion and a decrease in the cardiomegaly.

The most common diets include only milk, mashed potatoes and cereals, as in the case reported, and exclude meat and other iron-containing foods. Occult blood loss from the gastrointestinal tract was investigated by Hoag et al.,[5] utilizing radioiron studies. In thirteen infants with iron deficiency anemia they found that loss of whole blood in the stool varied from 7 to 107 milliliters over a three to four-week period. They did not elaborate on the cause of this blood loss.

Diagnosis of Iron Deficiency

The diagnosis of iron deficiency anemia is based upon an awareness of its possible occurrence, knowledge of susceptible infants, and appropriate laboratory studies. Hematologic studies show microcytosis and hypochromasia indicated by low red-cell indices. Stained smears of the peripheral blood confirm these findings and are more reliable when the anemia is severe, since the accuracy of hemoglobin determinations and erythrocyte counts is poor at low values. Thalassemia* and iron-loading anemias may have similar findings but can be differentiated by serum iron determinations. In iron deficiency the serum iron is low (less than 20 micrograms) and the total iron-binding capacity is increased.

Therapy for Iron Deficiency

The choice of iron-containing medication from the wide variety of medications now available for pediatric use can be easy if certain basic facts of iron therapy are kept in mind: (1) ferrous iron is better absorbed than ferric; (2) ferrous sulfate is the cheapest form of iron available; and (3) the response to ferrous sulfate is prompt and reliable. The therapeutic dose is 1.5 to 2.0 milligrams of elemental iron per kilogram of body weight, given three times a day. If preparations containing ferric iron are used, amounts greater than 2.0 milligrams per kilogram must be given. Response to adequate replacement therapy is prompt. Reticulocytosis occurs within five to ten days of treatment, followed by a rise in hemoglobin concentration. The latter is usually at normal level by two months. Therapy is continued for a month after normal hemoglobin concentrations are achieved, in order to improve body stores of iron. If no improvement occurs after one month of adequate therapy, iron administration should be stopped and the diagnosis re-evaluated, as the continuation of iron therapy over long periods may lead to hemosiderosis in patients with hemolytic or hypoplastic anemias. More important, other serious disorders may go unrecognized.

Transfusions are generally not indicated and may be dangerous in the presence of borderline cardiac compensation. If the hemoglobin concentration is below 4 to 5 grams per 100 milliliters of blood, it is usually safer to employ transfusions — preferably packed red cells. The amount of blood given should not exceed 10 milliliters per kilogram of body weight, as it is not necessary to raise hemoglobin concentrations above 7 to 8 grams per 100 milliliters of blood by transfusion. In the case reported, myocardial decompensation was first brought under control with appropriate medical therapy followed by immediate transfusion. Transfusion alone would probably have aggravated the cardiac failure and perhaps caused the death of the infant.

Summary

The case of a one-year-old infant with congestive myocardial failure on the basis of severe iron deficiency anemia is reported. The cardiac status returned to normal following appropriate therapy, and at 18 months

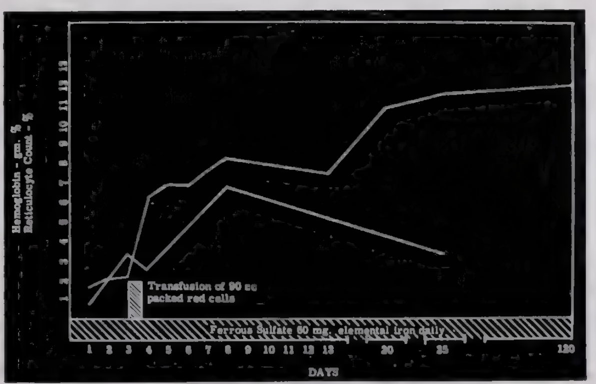

Fig. 3 — Response of hemoglobin and reticulocyte count to oral iron therapy. (Elemental iron 60 mg./day).

---

*See Test Your Word Score Page 943.

of age the hemoglobin concentration was normal, and there were no cardiac abnormalities.

Iron-deficiency anemia in infancy may occur by any one or more of four mechanisms. These are: (1) deficient iron stores at birth, (2) rapid growth rates of small and premature infants, (3) iron-deficient diets and (4) blood loss. Hematologic studies reveal a hypochromic, microcytic anemia, a low-mean corpuscular hemoglobin concentration, low serum iron levels and an increase in total iron-binding capacity.

Ferrous sulfate is the drug of choice in iron-deficiency anemia. The indications for transfusion are presented, and the use of packed red cells rather than whole blood is recommended.

Communication Barriers Between Medical Students and Their Psychiatric Patients[*]

ADELINE U. MANDEL, M.S.W., A.C.S.W.[**]
SHEROD L. MILLER, M.S.W.[†]
FLOYD K. GARETZ, M.D.[‡]
Minneapolis, Minnesota

THE RESEARCH for this paper grew out of an interest of members of the staff of the Psychiatry Outpatient Clinic of the University of Minnesota Hospitals in the incidence of patients with psychiatric problems in a general medical clinic and in the evaluation of such patients. Our goal was to learn something of the percentage of patients in a general medical setting who indicate that they have psychiatric problems and to learn also something of the way in which such patients are evaluated.

In order that the reader will better understand the nature of this research, the authors believe that it will be helpful to describe the setting in which the research occurred. The Comprehensive Clinic Program is an attempt to provide the medical student with the experience of having overall responsibility for patient care. The student starts with the patient in New Medicine Clinic and participates in the evaluation and treatment of all his patients in the various specialty clinics. He comes with his patient to Psychiatry Clinic one-half day per week for the entire six months. Here through the mechanism of small group supervision and direct contact with staff social workers, psychologists and psychiatrists, he evaluates and in some instances provides psychotherapy for his patients.

Data

The data of this research were derived from two main sources. First, all patients in the study were asked to complete a simple, short questionnaire. The questionnaire was completed during the patient's first visit to New Medicine Clinic. After the questionnaire was completed, it was sealed in an envelope and was not available to examiners conducting the regular clinical evaluation of the patient.

The manner in which the patients answered the questionnaire led to classification of patients into several groups. A patient was considered to have indicated that he had psychiatric problems if he answered affirmatively any two of the questions which specifically referred to mental, emotional or psychological concerns. A patient was considered to have asked for psychiatric help if he answered affirmatively the question regarding his wish to see a social worker, psychiatrist or psychologist for help with his problem.

---

[*] The authors wish to thank the many patients and hospital personnel who helped in this study.

[**] Psychiatric Social Work Supervisor and Clinical Instructor, Outpatient Psychiatry Clinic, University Hospitals, Minneapolis, Minnesota.

[†] Senior Psychiatric Social Worker, Outpatient Psychiatry Clinic, University Hospitals, Minneapolis, Minnesota.

[‡] Assistant Professor, Department of Psychiatry and Neurology, University of Minnesota Medical School, Minneapolis, Minnesota.

One sample of patients was accumulated in June and July, 1964. This sample consisted of 147 patients and was characterized by the fact that the medical students seeing these patients were just beginning their experience in the Comprehensive Clinic Program. A second sample of 71 patients was accumulated in September and October, 1964, after the students had passed the half-way mark in their experience in the Comprehensive Clinic Program.

The second kind of data collected for this research came from clinical records of the patients. The records of each patient in the study were reviewed carefully by one of the authors. Special attention was paid to (1) whether or not there was any mention in the current record of mental, emotional, family or psychological problems; and (2) whether or not there was a psychiatric referral or consultation and/or treatment in the psychiatric clinic. Review of the charts was begun approximately four weeks after the patient's initial visit in New Medicine Clinic.

From the information gathered from the clinical records, a classification of patient groups was made. If anywhere in the current New Medicine work-up there was mention of a psychiatric problem, it was considered that the examiner in that case had recognized the presence of a psychiatric problem in the patient. If referral or consultation occurred, either through the facilities in our own hospital or facilities elsewhere in the community, it was considered that the patient had been referred for psychiatric evaluation.

Results

Table 1 is a summary of results regarding the incidence of psychiatric problems in 218 patients in a general medical setting. The data of Table 1 suggest that there is a significant difference between the percentage of patients who report psychiatric problems on a questionnaire as compared to the percentage of patients in the same sample perceived by medical student examiners to have psychiatric problems. There is also a significant

Dear Patient:

We ask your cooperation in answering the following questions just as you feel today. We hope that by so doing we can get a better understanding of your problems.

Answer Yes or No.	Yes	No
1. Have you been ill for a long time?	______	______
2. Did you have treatment for your illness before coming here?	______	______
3. Do you tend to worry a lot about your health or other matters?	______	______
4. Do you have trouble eating or sleeping?	______	______
5. Do you feel you have psychological problems?	______	______
6. Do you tend to cry a great deal?	______	______
7. Are you satisfied with your life?	______	______
8. Do you quarrel with others easily?	______	______
9. Have you been in trouble during the past year?	______	______
10. Are you very unhappy about anything which concerns your family, your job or relationships with people?	______	______
11. Do you want to discuss these problems with someone in the University Hospitals, namely:		
A. Social worker	______	______
B. Psychiatrist	______	______
C. Psychologist	______	______

Please enclose this in envelope, seal and give to nurse.

Figure — A Copy of the Questionnaire Used in the Study difference between the percentage of patients who asked for help as compared to the percentage of patients in the same sample who were referred for psychiatric consultation.

Table 2 is a summary of data with further breakdown of the sample in terms of age, sex and marital status.

Table 2 is a complex compilation of data and needs further explanation. The total sample of 218 patients was analyzed in terms of three variables: age, sex and marital status. Patients were divided into under age 49 and over age 49; male and female; married and unmarried. Then the data was examined in terms of the sub-groups of age, sex and marital status to determine the influence of these three variables on (1) the percentage of patients who indicated they had psychiatric problems, (2) the percentage of patients in whom psychiatric problems were recognized by the examiner, (3) the percentage of patients who asked for psychiatric help, and (4) the percentage of patients who were referred for psychiatric evaluation. There were more of the younger group, more females, and more unmarried patients in every category.

Percentage differences were calculated. For example (column one, line one of the table) 14 per cent more patients under age 49 indicated they had psychiatric problems than patients over 49. This difference was significant at the five per cent level. As another example, the difference in percentage between male and female patients who asked for psychiatric help was only three per cent. This was not a statistically significant difference.

Table 2 also has some other interesting aspects. If we consider two percentage differences, for example, we find that there is a three per cent difference between males and females who asked for help and a six per cent difference between male and female patients who were referred for psychiatric evaluation. The difference between six per cent and three per cent was not found to be statistically significant. However, considering the difference between males and females who indicated they had problems (12 per cent) and the difference between males and females who were recognized by an examiner as having psychiatric problems (31 per cent), this difference of 19 per cent is statistically significant.

Table 3 is a summary of data comparing

TABLE I

A Summary of Data Regarding the Incidence of Psychiatric Problems in 218 Patients in a General Medical Clinic

Patients indicated they had problems on a questionnaire	54%	p .01
Examiner recognized the presence of a psychiatric problem	32%	
Patients indicated they had problems and asked for help	26%	p .05
Examiners referred patient to psychiatry	17%	

TABLE 2

This is a summary of data regarding percentage differences when the sample of 218 patients was analyzed as to age, sex and marital status. The percentages shown in each of the columns designated age, sex and marital status refer respectively to the following: differences between patients under age 49 as compared to patients over 49; differences between male and female; differences between married patients and unmarried patients. The left hand column refers to the particular aspect of the data for which the percentage differences occurred. "Indicate" means patients indicated they had psychiatric problems. "Recognize" means examiner recognized the presence of psychiatric problems. "Help" means the patient asked for psychiatric help. "Referred" means the patient was referred for psychiatric evaluation.

	Age	Sex	Marital Status
Indicate	14% $p < .05$	12% $p < .1$	14% $p < .05$
Recognize	13% $p < .05$	31% $p < .01$	11% $p < .1$
Help	18% $p < .01$	3% $p < .5$	16% $p < .02$
Referred	21% $p < .01$	6% $p < .5$	13% $p < .05$

how patients answered the questionnaire and the course of the patient's evaluations. The data of Table 3 suggest that training and experience increase the student's ability to recognize psychiatric problems in their patients and also to better deal with these problems when recognized. Although none of the percentage difference in Table 3 reached statistical significance at the five per cent level, the consistency of difference of direction suggests that the difference might reach statistical significance, were the sample larger.

Conclusion

The following conclusions appear warranted from the data of this research: (1) previously reported clinical observations are confirmed in that a significant percentage of patients in a general medical clinic report or are perceived as having psychiatric problems. (2) There is a difference in the percentage of patients who report psychiatric problems on a questionnaire as compared to the percentage of patients in the same sample perceived by the medical student examiner to have psychiatric problems. This is thought by the authors to reflect difficulties of communication between students and their patients about psychiatric problems. Not all patients who asked for help with psychiatric problems were referred for psychiatric evaluation. The two major reasons for this are thought to be that students do not always recognize psychiatric problems and are not always aware of appropriate ways of dealing with such problems, even if they are recognized. (3) It appears that experience and training increase the medical student's ability to communicate with his patients regarding psychiatric problems and also to cope better with such problems when they are recognized. Both the percentages of recognition and referral increase with experience. (4) The problems of students in communicating with patients regarding psychiatric problems do not appear to result from stereotypes or preconceptions students might have about patients regarding age or marital status. It does appear, however, that medical students do perceive female patients as having more problems than male patients. (5) The review of clinical records by the authors revealed a total of 20 patients in groups I and II who had problems generally described as psychosomatic or psychological, such as ulcers, asthma, headaches, low back pain, etc. Since none of these patients were referred for psychiatric treatment by the student examiner, one may assume that the student examiners viewed these problems as organic rather than as having psychological implications. (6) The data of this investigation indicate the need for further explorations of methods and content of communication between student physicians and their patients. We particularly need to help students understand their patients in terms of personal, emotional, mental and family concerns.

Summary

This research is a study of 218 outpatients seen for initial medical evaluation in a general medical setting. The patients were seen by senior medical students under staff supervision. On a questionnaire 54 per cent of the patients indicated that they had psychiatric

TABLE 3

This is a summary of data comparing how patients answered the questionnaire and the clinical course of each patient's evaluation. "Inexperienced" refers to patients seen by "inexperienced" medical students (those in the first two months of experience in Comprehensive Clinic Program.) "Experienced" refers to patients seen by "experienced" medical students (those past the half way mark in their experience in the Comprehensive Clinic Program.)

Patients Indicated They Had Psychiatric Problems	Recognized by Examiner	Referred to Psychiatry
Inexperienced	49%	25%
Experienced	60%	37%
Patients Who Asked for Help		
Inexperienced	63%	39%
Experienced	76%	52%

problems, confirming other observations that psychiatric problems are extremely common in a general medical setting.

This research investigates communication barriers between medical students and their patients and finds that students frequently cannot communicate with their patients about psychiatric problems. However, as students become more experienced under supervision, their ability to communicate with patients improves.

Frequent areas of difficulty for students appear to be with patients who have psychophysiologic disorders. Also, students tend to over-react to problems in female patients.

Papyrus Ebers[*]

To Eliminate Tapeworms in Ancient Egypt

Wormcakes were recommended first. One cake was composed of Herbs-of-the-Field and Natron, baked into a cake with Cow's Bile. Another was compounded of Herbs-of-the-Field and Heart-of-the-mesa-Bird, along with Honey, Wine, and Sweet Beer. Or a draught could be used.

Red-lead	1
gentet-plant, nesxi-corn, ta-bread	1
Petroleum	1
Sweet Beer	1

Stir, powder, strain, and take for one day.

And desperate cases could resort to a poultice:

Resin-of-Acanthus	1
Blossoms-of-the-Peppermint	1
Wild Lettuce	1
t'as-plant	1

Stir, mix into one, and apply as a poultice to the Body of the Man or Woman.

That some of the patients after a course of treatment on the lines indicated should complain of anal discomfort is not a thing for wonder. Consequently it occasions no surprise to find a large section devoted to relieving this sequela. As usual the thing was done thoroughly. Internal remedies were first prescribed:

Remedy to Cool the Anus

Onion-meal	1/32
Tail-of-a-Mouse	1/32
Honey	1/4
Water	1/3

Strain and take for four days.

A suppository was next recommended:

Fat-of-the-Antilope	1
Caraway	1

Roll into a Pill and put in the Anus

Another Remedy Against Sores in the Anus

Egg-of-the-Goose	1
Guts-of-the-Goose	1

Clap on the anus.

Anti-Nuclear Antibodies

THE PURPOSE of this study is to report the incidence of circulating anti-nuclear antibodies in a variety of clinical conditions. The demonstration of such antibodies may aid in the diagnosis of certain diseases and possibly indicate an auto-immune mechanism operative in some of them. The need in diagnostic laboratories for a new immunochemical method to detect the anti-nuclear antibodies may be summarized as follows:

The conventional lupus erythematosus clot test has been negative in a considerable number of histologically proven systemic lupus erythematosus cases. Dubois[1] stated that such clot tests had been positive in 50% of systemic lupus erythematosus patients. Lupus erythematosus cell formation is a complex immunobiological event which can be interfered with by a number of factors, such as anti-complementary effect and the

inhibitors of the patient's blood. The factor which is responsible for the lupus erythematosus cell formation is an auto-antibody directed against the DNA-protein complex of the nucleus. Other auto-antibodies such as anti-histone, anti-DNA, and anti-soluble nucleoproteins may be present in the absence or presence of the lupus erythematosus factor; but these do not seem to participate in lupus erythematosus cell formation. The present technique, fluorescent anti-nuclear antibody, appears to overcome these difficulties in that it is not affected by the interferences in the patient's blood or otherwise, and it can detect all the auto-antibodies directed against the nuclear constituents. Furthermore, in the auto-immune-group diseases, anti-nuclear antibodies have been more commonly encountered, so that such a method might constitute a broad-spectrum, auto-immune screening test.

Materials and Methods

The sera of 612 patients were sent to our laboratories by various services of the University of Minnesota Hospitals, Glenwood Hills, Fairview, and St. Mary's Hospitals of Minneapolis. The fluorescent anti-nuclear antibody test was run once in the majority of cases, with the sera of 132 blood bank donors serving as controls. In almost all cases, the clinical diagnosis was not known at the time that the test was performed; the diagnosis listed in the present study was obtained by chart reviewing at a later date. The fact should be stressed that a few of these patients were diagnostic problems and the diagnosis taken from the chart might not be the accurate final diagnosis.

The method of the fluorescent anti-nuclear antibody (FANA) test has been published in detail by one of us.[2] Briefly, the technique may be summarized as follows: Blood smears of normal individuals were used for the source of leukocyte nuclei. The smears were incubated with patients' sera to let the antigen-antibody reaction take place; then they were washed in a suitable buffer solution to eliminate unbound non-antibody proteins. Finally, the smears were treated with fluorescent-labeled anti-human gamma globulin which would detect the gamma globulin antibodies bound to the nuclei of leukocytes.

Results

The results are summarized in Tables 1-8. Five per cent of the 132 blood-bank donors showed a positive reaction. Table 1 includes the collagen disease group which exhibits a very high incidence of positive anti-nuclear antibody test:

Systemic Lupus Erythematosus

Ninety per cent of 44 cases were positive. Four negative cases were in complete remission. Although the lupus erythematosus clot test was not run concurrently with the fluorescent anti-nuclear antibody test, almost all of these 44 cases were a diagnostic problem with repeatedly negative lupus erythematosus clot tests. The fluorescent anti-nuclear antibody test can become negative during the course of immunosuppressive therapy if an adequate remission takes place.

Discoid Lupus Erythematosus

Fifty-nine per cent of 54 cases were fluorescent anti-nuclear antibody test positive. All of these cases had a negative lupus erythematosus clot test. Positive cases were predominantly women. Detailed study in many of these patients had been published.[3]

Rheumatic Fever

There was fifty per cent positivity in 28 patients who were mostly at the recurrent active stage of the disease.

Rheumatoid Arthritis

Thirty-five per cent of the 74 cases were positive, and positive cases were again predominantly females who showed a high titer rheumatoid factor in the sera. Positive cases also tend to have more systemic manifestation of the disease, i.e., fever, muscular pain, pleuritis, etc. Two of the positive patients' courses were complicated with diffuse vasculitis while they were on corticosteroid therapy. Another two positive patients complained of dryness in the mouth and in the eyes with mild swelling of the parotid glands. These two cases might be classified as Sjögren's syndrome.*

Other Collagens

Polyarteritis nodosa cases showed a 75% incidence of positivity. Negative scleroderma cases had the disease localized in the skin.

Liver Diseases

Table 2 summarizes the results: postnecrotic cirrhosis and plasma cell hepatitis cases combined exhibited very high percent positivity — 80%. Laënnec's cirrhosis showed 50% positives.

Blood Diseases

Results are summarized in Table 3. Although a small number of cases were included in this group, a significant number of positivities were observed in idiopathic thrombocytopenic purpura and auto-immune hemolytic anemia.

Skin Diseases

Conditions listed in Table 4 were negative, except one case with Raynaud's phenomenon and one of erythema nodosum. The latter case was a woman who received deep X-ray therapy for a carcinoma of the uterus and developed fever and erythema nodosum one day later. Her lupus erythematosus clot test was also positive.

Neuropsychiatric Disorders

A significant number of patients with multiple sclerosis (Table 5) were positive, as reported earlier in other groups of patients.[4] Occasional positivities were recorded in cases of acute polyneuritis (Guillain Barré syndrome) and radiculitis.

Metabolic Conditions

As seen in Table 6, the cases of nontoxic goiter were positive.

TABLE 6
Anti-nuclear Antibodies
in Metabolic Conditions

Diagnosis	Positive	Total
Nontoxic Goiter	3	4
Hypothyroidism	1	5
Thyroiditis	1	6
Hyperthyroidism	0	3
Diabetes Mellitus	1	8
Arteriosclerosis	2	13

Various Other Diseases

Table 7 shows a group of various diseases which exhibited a definitely higher percentage of positivity than a normal control group. Among those, the following conditions deserve to be mentioned: All three positive patients with bronchial asthma were nonallergic after the age of forty and had high blood eosinophils and negative lupus erythematosus clot tests. Three of the fifteen cases with glomerulonephritis were interesting: One had a positive lupus erythematosus clot test but showed no other systemic involvement of his disease. The second was a young woman with chronic nephritis and a negative lupus erythematosus clot test. The third patient was also a young female with a negative lupus erythematosus clot test, who probably had lupus erythematosus. All four positive fluorescent anti-nuclear antibody test cases of diffuse carcinomatosis were in women, being primarily either of the breast and/or of other female organs. Almost all had pleural effusion without tumoral involvement, hemolytic anemia, fever and joint manifestations. It is also interesting to note the presence of positive cases with pyelonephritis and regional enteritis. One of two positive pericarditis patients developed nephritis a few months later, and the diagnosis was changed to systemic lupus erythematosus. Her lupus erythematosus clot tests were negative.

---

*See Test Your Word Score Page 943.

Cases with negative fluorescent anti-nuclear antibody test, who were not included in any of the tables, were diagnosed as having acute bronchitis, pneumonia, cholecystitis, upper respiratory infections, hypertension, etc.

Comment

The high incidence of positive anti-nuclear antibodies in the collagen disease group is expected in view of the auto-immune process demonstrated in such a disease as systemic lupus erythematosus. It is, however, interesting as well as surprising to find 50% positivity in rheumatic fever or in rheumatic heart disease cases. The relationship between rheumatic fever and beta streptococcic infections has been well documented. Kaplan[5] recently reported that human heart muscle and the wall of streptococci possessed common antigens.

TABLE 7

Pyelonephritis	3	5
Regional Enteritis	3	4
Ulcerative Colitis	1	4
Thrombophlebitis	0	6

The fluorescent anti-nuclear antibody test offers a valuable aid in making the diagnosis of systemic lupus erythematosus, especially in the cases that have negative lupus erythematosus cell tests. It should be stressed again that the positive fluorescent anti-nuclear antibody test is by no means diagnostic for any condition.

Rheumatoid arthritis patients with a positive fluorescent anti-nuclear antibody test tend to show more systemic manifestations. It is possible that these cases form a group between systemic lupus erythematosus and rheumatoid arthritis.

Postnecrotic cirrhosis and a variant of postnecrotic cirrhosis, plasma cell hepatitis, are two other conditions with a high incidence of positive fluorescent anti-nuclear antibody. This may serve as a differential diagnostic test between these conditions and the surgical jaundice cases, tumors of the liver, etc. . . Since a preceding viral hepatitis is suspected in the majority of postnecrotic cirrhosis cases, a cirrhosis stage might be the auto-immune phase of viral hepatitis, analogous to the above rheumatic fever speculation. This may also apply to Laënnec's cirrhosis in that the initial insult may be metabolic, not infectious.

In addition, as seen in Table 8, positive fluorescent anti-nuclear antibody was ob-

served in cases of auto-immune hemolytic anemia, idiopathic thrombocytopenic purpura, glomerulonephritis, pyelonephritis, regional enteritis, and multiple sclerosis. Whether or not fluorescent anti-nuclear antibody-positive cases of idiopathic thrombocytopenic purpura and auto-immune hemolytic anemia would eventually go into the systemic lupus category remains an interesting possibility. With a preceding streptococcic infection for glomerulonephritis and a bacterial pyelitis for pyelonephritis, these conditions can be compared with rheumatic fever. Positive fluorescent anti-nuclear antibody in cases of regional enteritis and multiple sclerosis could lead us to an auto-immune type approach in the pathogenesis of these conditions.

Positive anti-nuclear antibodies were detected in the blood of relatives of systemic lupus erythematosus patients who were asymptomatic.[6] Such findings could explain occasional positivity observed among the normal individuals, although no attempt was made along this line during the present study. Presently, we are using quantitative fluorescent anti-nuclear antibody since low titers appear to be present in these positive normal controls, the blood relatives of systemic lupus erythematosus patients, postinfectious states, etc. . . Further studies along this line are in progress.

Positive cases with carcinomatosis were also interesting in that they exhibited hemolytic anemia, joint pain, and pleural effusions. These may represent a tumor immunity, i.e., the immune response of the host to the tumor. One of these cases was particularly typical for this type of response in that the patient reacted violently to the deep X-ray therapy: she developed high fever, hemolytic anemia, and erythema nodosum.

It is difficult to compare the present result with those obtained by Weir et al.,[7] due mainly to the selection of cases and the difference in the techniques. One important difference was with the cases of rheumatic fever, in that none of the 56 rheumatic fever cases showed positive anti-nuclear antibodies in their sera.[7]

Summary

Anti-nuclear antibodies were sought in the sera of 612 patients by the indirect immunofluorescent technique. The sera of 132 normal individuals served as controls. Anti-nuclear antibodies were found in 90% of the cases of systemic lupus erythematosus, 59% of the cases of chronic discoid lupus erythematosus, 35% of the cases of rheumatoid arthritis, 50% of the cases of rheumatic fever, 35% of the cases of multiple sclerosis, 80% of the cases of chronic hepatitis, and 75% of the polyarteritis nodosa cases. Occasional positive results were observed in auto-immune hemolytic anemia, idiopathic thrombocytopenic purpura, glomerulonephritis, pyelonephritis, dermatomyositis, regional enteritis and carcinomatosis.

Achievement

If you have built castles in the air, your work need not be lost. Now put foundations under them. — Osa Johnson

Pro-Banthīne®
(propantheline bromide)

Intragastric photography has provided a new and precise method of measuring the effectiveness of anticholinergic drugs. The transition from gastric motor activity to relaxation seen with effective doses of such drugs takes only a few seconds and is easily demonstrated.

The importance of vagal stimulation of gastric hyperacidity and hypermotility makes such measurements particularly important in evaluating the parasympatholytic effect of drugs used in patients with peptic ulcer, gastritis, biliary dyskinesia and other gastrointestinal disorders.

Pro-Banthīne has been shown[1] to produce complete gastric motor inactivity with doses of 6 to 8 mg. intravenously. Comparison tests were made with the belladonna fraction, atropine. Measured usual dosage unit versus usual dosage unit, Pro-Banthīne was more than four times as effective as the belladonna alkaloid.

Indications: Peptic ulcer, functional hypermotility, irritable colon, pylorospasm and biliary dyskinesia.

Oral Dosage: Adequate dosage should be given for optimal results. For most *adult* patients this will be four to six 15-mg. tablets daily in divided doses. In severe conditions as many as two tablets four to six times daily may be required. Pro-Banthīne (brand of propantheline bromide) is supplied as tablets of 15 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type ampuls of 30 mg.

Side Effects and Contraindications: Urinary hesitancy, xerostomia, mydriasis and, theoretically, a curare-like action may occur. Pro-Banthīne is contraindicated in patients with glaucoma, severe cardiac disease and prostatic hypertrophy.

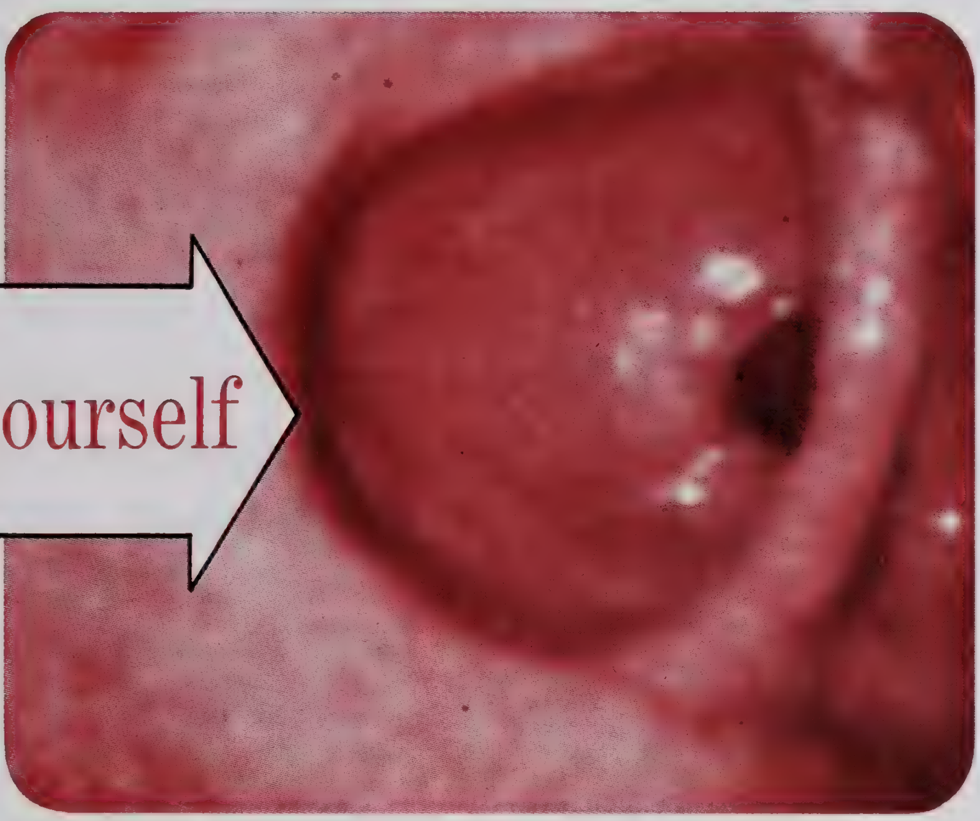
See for

Is Effective

yourself



Complete gastric relaxation with Pro-Banthīne. As this intragastric photograph demonstrates, gastric relaxation is attained with 6 mg. of Pro-Banthīne intravenously; the antrum is relaxed and the pyloric orifice remains open. Full intravenous doses of atropine (4 mg.) produce no measurable effect.

BE A MYTH-MONGER #1

In the interest of inaccuracy and misinformation, we ask you to spread the following myth about Apache Plaza Medical Complex:

APACHE PLAZA MEDICAL COMPLEX IS TOO EXPENSIVE.

To be completely fair, some doctors think that's *not* a myth. For half the cost they can rent space above a beer joint in a run-down neighborhood. But, for the doctor who buys top-flight equipment, hires first-rate help, and avoids buying used cars because he doesn't want to take on someone else's problems . . . for that doctor, Apache Plaza Medical Complex makes sense. And it isn't expensive. It's just first class.

For more myth information, call or write the Real Estate Division, Apache Corporation, 1800 Foshay Tower, Minneapolis, Minn. 55402. Telephone: (612) 339-7781.

Staphylococcic (Pseudomembranous) Enterocolitis

ACUTE ENTEROCOLITIS with a pseudomembrane has been described many times during the last 30 years. At first, most papers reported only postoperative cases and particularly cases following subtotal gastrectomy or colectomy. Fluid and electrolyte losses were severe, and shock was common. Autopsy showed a pseudomembrane lining the small bowel and colon, as well as loss of the superficial layers of the intestinal mucus membrane. Death was frequent.

Similar intestinal lesions in patients with ileus, diarrhea, dehydration and shock have been described in cases of hemorrhagic shock, congestive heart failure, myocardial infarction and acute infections.

During the past two decades a common antecedent in these patients has been the administration of antibiotics. The antibiotics were usually given by mouth, and the tetracyclines were most often responsible. A review of the clinical records in one local hospital showed 109 cases of acute staphylococcal enterocolitis during the past decade.[1] Every one of these patients had been receiving antibiotics at the onset of the condition. Usually these were antibiotics given to suppress the normal colonic bacterial flora as an aid in intestinal surgery or in cases of threatening hepatic coma. In every case antibiotic-resistant staphylococci were found in huge numbers in the diarrheal stool or in the contents of the gut, and almost no coliform organisms had survived. The staphylococci found in the feces were invariably resistant to the antibiotics in use in the patient. Mild cases responded well when the antibiotics were discontinued and losses of fluids and electrolytes were replaced. Severe cases required the addition of a specific antibiotic to suppress the overwhelming growth of virulent staphylococci. Various antibiotics were tried. The most effective antibiotic seemed to be vancomycin (Vancocin-Lilly) given by mouth or through a nasogastric tube, 0.5 gm. in water every four to six hours for three to five days. Among 45 patients treated with vancomycin, there were no deaths attributed to the staphylococcal enterocolitis.

In patients with other staphylococcal infections, such as pneumonia or wound infection, therapy with parenteral methicillin or oral oxacillin would seem advisable. These penicillinase-resistant penicillins can be expected to be effective against the enterocolitis and the nonenteric infection as well. Furthermore, they have little toxicity, and they do not inhibit the intestinal coliform bacteria.

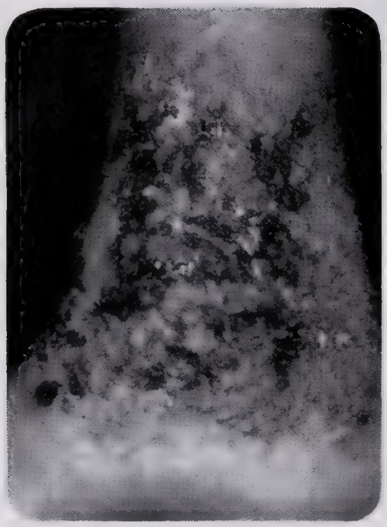
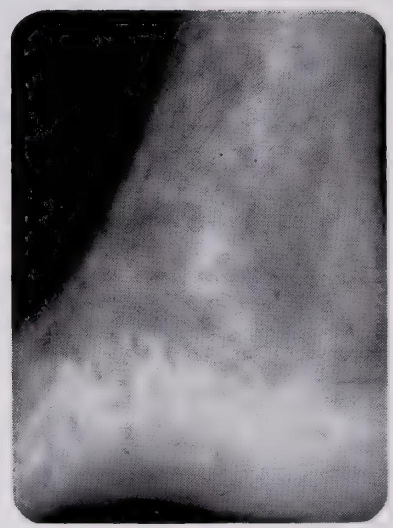
eczema: scourge of childhood



R. R., Age 11—Before treatment—
atopic eczema of long standing



After treatment—with ARISTOCORT
Topical Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of childhood eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive nonpermeable dressings, may result in systemic absorption. Appropriate precautions should be taken. When occlusive nonpermeable dressings are used, miliaria, folliculitis and pyodermas will sometimes develop. Localized atrophy and striae have been reported with the use of steroids by the occlusive technique. When occlusive nonpermeable dressings are used, the physician should be aware of the hazards of suffocation and flammability. The safety of use on pregnant patients has not been firmly established. Thus, do not use in large amounts or for long periods of time on pregnant patients.

Packages: Tubes of 5 Gm. and 15 Gm.; ½ lb. jar.

portrays a severe case of staphylococcal pseudomembranous enterocolitis following a gastrectomy and requiring colectomy. Secondary infections, apparently caused by Pseudomonas and Monilia, led to recurrent colitis and fatal pyelonephritis. These late complications are unusual in staphylococcal enterocolitis but serve to illustrate the possibilities for trouble after recovery from the acute phase of pseudomembranous enterocolitis.

Acid-Base Metabolism

THE DEVELOPMENT and commercial production of sensitive and stable electronic pH meters and accurately thermostated micro pH electrodes have made available accurate, precise, and rapid technics for acid-base determination. The more recently developed pCO_2 electrode may simplify and increase the accuracy of these determinations even further. Consequently, clinical laboratories, in rapidly increasing numbers, are making these tests available for routine performance when ordered by the clinicians.

In the article by Eichenholz et al.,* the importance of determining three variables, pH, pCO_2 and bicarbonate ion, to diagnose disturbances in acid-base balance is emphasized. Their data can be added to the literature that stresses that the serum electrolytes (sodium, potassium, chloride, and CO_2 combining power) are not reliable indicators of acid-base balance and, in fact, may even be quite misleading at times.

Ideally, arterial blood should be used. In addition to obtaining the blood with a heparinized syringe from the brachial or femoral artery, the sample may be obtained from the radial artery, using a heparinized vacuum tube.[1] The validity of using heparinized vacuum tubes instead of sealed syringes for accurate routine determinations has been demonstrated.[2] Capillary and venous blood which has been arterialized by the application of heat is also satisfactory. If absolutely necessary, venous blood may be used since, in general, the arterial-venous pH difference ranges only between .01 and .03 pH units in the resting patient, with the venous blood being more acid.[3]

Eichenholz et al. chose to correct the actual bicarbonate concentration (with complete oxygenation) to a standard pH of 7.40 instead of to a standard pCO_2 of 40 mmHg.; this later correction, incidentally, represents the "standard bicarbonate" of Astrup, as first advocated by Hasselbalch.

Theoretically it is somewhat more desirable to use a standard pH rather than a standard pCO_2.[4] This correction of the plasma bicarbonate for the buffering effect (primarily hemoglobin) of whole blood to pH 7.40 is made in an attempt to classify and quantitate the type and degree of acid-base disturbance, i.e., whether respiratory, metabolic, or mixed, and the amount of excess or deficit of base. The authors demonstrated the usefulness of this correction by distinguishing a mixed respiratory-metabolic acidosis from an uncompensated respiratory acidosis in two patients (one polycythemic, the other anemic), both of whom had identical pH, pCO_2 and $[HCO_3^-]$ values. The use of $[HCO_3^-]$ 7.40 in anemic or polycythemic patients serves to emphasize

Thanks to Dexamyl®

brand of
dextroamphetamine
sulfate and amobarbital

she can say "No thank you" to the crêpes suzette.

'Dexamyl' does more than most anorectics. Because it curbs appetite *and* lifts mood, 'Dexamyl' can encourage the discouraged dieter to stay on her diet.

The mood lift with 'Dexamyl' can make the difference between the success or failure of her diet plan.

Formulas: Each 'Dexamyl' Spansule® Capsule (brand of sustained release capsule) No. 1 contains 10 mg. of Dexedrine® (brand of dextroamphetamine sulfate) and 1 gr. of amobarbital, derivative of barbituric acid [Warning, may be habit forming]. Each 'Dexamyl' *Spansule* capsule No. 2 contains 15 mg. of Dexedrine (brand of dextroamphetamine sulfate) and 1½ gr. of amobarbital [Warning, may be habit forming].

Principal cautions and side effects: Use with caution in patients hypersensitive to sympathomimetics or barbiturates and in coronary or cardiovascular disease or severe hypertension. Insomnia, excitability and increased motor activity are infrequent and ordinarily mild.

Before prescribing, see SK&F product Prescribing Information.

Smith Kline & French Laboratories SK&F

the effect of changing hemoglobin concentrations on the CO_2 absorption curve. Increasing hemoglobin concentrations, of course, increase the slope of the curve, indicating greater buffering effect.

One of the basic assumptions underlying the use of $[HCO_3^-]$ 7.40 is that the response of whole blood in vitro to variations in pCO_2 will be the same as in the intact organisms. A recent study of "whole body" carbon dioxide titration curves in normal man[5] reveals that the in-vitro and in-vivo curves may be appreciably different. Astrup[6] emphasizes this difference when he states: "When dealing with patients, the amount of excess or deficit of base in the whole body does not always seem to be directly proportional to the amount of excess or deficit of base in the blood. When treatment of patients with intravenous infusions of acid or base is demanded, it is therefore advisable to estimate the dose necessary to normalize the base content of the extracellular space only, and then follow the effect of the treatment by frequent blood analyses, and clinically as well, before new infusions are given. Thus, overtreatment is avoided."

Although the therapy for acid-base disturbance must of necessity be individualized, a second article stating general principles of therapy used by the authors, based on the parameters they determine, would be extremely valuable.

Technique of Laryngoscopy*

THE THORNELL arytenoidectomy technique using suspension laryngoscopy has proved to be an extremely successful and most gratifying procedure for patients suffering from bilateral paralysis of the vocal cords. Unfortunately, the use of the Killian-Lynch suspension laryngoscope is seldom taught to residents in our teaching centers. In a survey conducted in 1964, J. C. Lillie found that most direct laryngoscopic examinations in the residency training programs in the United States are done either with the Jackson-type laryngoscope or some modification of it. Although 52 institutions replied that the Killian-Lynch suspension apparatus was used, most said that it was used infrequently and at most for not more than 15% of the cases. Dr. Lillie deduced that only about one half of the residents trained in otolaryngology in this country have seen suspension laryngoscopy performed.

Thornell's keen mind perceived that suspension laryngoscopy was ideally suited for transoral arytenoidectomy and proceeded to perfect his technique without any encouragement from his mentors, who were considered experts in the use of the Killian-Lynch suspension laryngoscope. Perhaps if more teaching centers were familiar with suspension laryngoscopy, this technique would be more widely used.

Soyalac **SOLVES THE PROBLEM**

. . . and BABY APPROVES!

Baby has a thing or two to say about a hypo-allergenic, milk-free diet!

Soyalac is the good-tasting, fibre-free formula that infants readily accept. The exclusive Soyalac process results in a consistency much like milk, with a light, creamy color—and nut-like flavor but without a trace of sediment.

Soyalac satisfies the infant. Strikingly similar to mother's milk, it provides protein of high biologic value and balanced nutrients. Clinical data furnish evidence of Soyalac's excellence in promoting normal growth and development.

Communication Barriers — An Ongoing Problem

IT HAS BEEN recognized by all physicians that a large percentage of their patients do not have structural or "organic" causes for their symptoms. As the general public has become increasingly psychiatrically oriented, the patient also has learned that his fatigue, pain, palpitation, dizziness, diarrhea, or any one of a myriad of other complaints may reflect his anxiety, depression anger, or other conflictual feelings. Since the therapeutic expert is almost solely dependent on his diagnostic acumen and, furthermore, since developments in the treatment of emotionally disturbed patients have been significant in recent years, it is even more important now than formerly to be aware of and able to diagnose the "functional" illness. This should not be construed as "separating the wheat from the chaff," because such an attitude reflects an element of condescension that cannot help but interfere with the empathetic understanding of the turmoil in the patient's life that is reflected by his symptoms.

In order for the physician to make the proper diagnosis, he must be able to communicate on the same level with the patient. He must also be willing to pursue leads in the patient's history that point toward evidences of conflict. These may involve family, job, finances, sexual activities, or other areas of concern to the patient. The physician is usually construed as a trusted confidant and is in an excellent position to tactfully question the patient with regard to life's difficulties. It is amazing how freely patients will discuss their problems and, often, in doing so will gain insight into their personal turmoils. The physician will also be in a better position to plan the therapeutic program whether it be reassurance, continued support with symptomatic treatment, or referral for more specialized evaluation.

Such interpersonal communication between the physician and his patient is the essence of the art of medicine. Yet it is largely a learned process. Some of the attitudes physicians have toward their patients undoubtedly reflect the physician's own personality. A part of this is contingent on his own private life and how well he has coped with his own anxieties. But another important aspect relates to the training period during the clinical years of medical school and busy internship services. The student at all levels learns from his teachers. This learning not only involves such things as how to discern a breast tumor by palpation, but also how to assay the patient's anxiety, communicate with her the importance of surgical consultation, and assess her fears of a mutilating operation. These latter, often equally important factors in the art of medicine, involve tact, understanding, compassion, and genuine empathy for the patient. Such abstract, emotionally-laden factors are more difficult to teach than are the more concrete aspects of medical practice — and even more difficult to learn; yet a grasp of these factors is imperative for the complete physician who genuinely wants to understand his patients and, therefore, to offer them the best care.

The data recorded by Mandel, Miller, and Garetz in this issue of Minnesota Medicine* highlight some of the barriers in communication between medical students and their patients. The initial difficulties in communication diminish with experience, although those of us long past medical-school clinics must also realize that the learning of the art of medicine is a never-ending process. We cannot learn too much about the vicissitudes of our patients, how they respond as individuals to stress, and how they communicate this via symptoms to us, their physicians.

"Chickens," said the colored philosopher, "is de usefulest animal dere is. You kin eat fo' dey is born an' after dey is dead." — Anon.

to help relieve pain in common anorectal disorders

"non-caine" Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form...both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.

DIOTHANE
OINTMENT
Soothing, Temporary Relief of Hemorrhoidal Pain, Rectal Itching
CHILD
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

Evolving Concepts in Vascular Surgery*

THE SURGEON'S POSITIVE attitude is sometimes surpassed only by his eagerness to simplify the complex. This attitude has or is meant to have the effect of giving confidence in the surgeon essayist. At the same time, however, a wary reader may well be sceptical of the positive and simplified approach to the treatment of clinical pathological states.

However appealing and direct the style and the sincere presentation of valuable facts regarding the treatment of vascular disorders, a few words of caution should be given.

A large experience with thrombophlebitis of the superficial and deep types will include the rare case of suppurative or phlegmonous** phlebitis requiring not only proximal ligation but treatment with antibiotics as well as drainage procedures. On the other hand superficial and sometimes deep thrombophlebitis may require only such simple measures as avoidance of prolonged sitting or standing, rapid walking, elastic support and elevation of the foot of the bed.

Embolization from superficial thrombophlebitis is rare and proximal ligation is rarely necessary. Such cases should be watched from day-to-day, and if actual progression is observed, proximal ligation may be in order. This is not to say that along with the conservative regimen mentioned above, and even with progression, further treatment by anti-inflammatory agents may not be tried.

Early venous thrombectomy in some cases of acute iliofemoral thrombophlebitis is a nonhazardous procedure which may speed convalescence. There is great doubt, however, that thrombectomy is as innocuous and as efficacious in the long run as proper conservative medical management alone. Hafner, Cranley, Krause and Strasser, mentioned as exponents of thrombectomy, say as much in their reports.

It is hoped that surgery for pulmonary embolectomy will be simplified; to do this more procedures must be attempted. At this time, however, to operate on a patient with suspected pulmonary embolism without angiographic studies and without cardiopulmonary bypass available is probably foolhardy and may result in many more fatalities than would conservative treatment. Supportive use of the cardiopulmonary apparatus as a partial bypass in appropriate cases until a diagnosis can be made and when indicated during the surgery should save many lives which would otherwise be lost.

In regard to direct arterial extracranial cerebral vascular surgery, a unilateral carotid artery stenosis of 75 per cent or more, thought to be of clinical significance, can still be evaluated by the results of preoperative trial occlusion. Loss of consciousness during trial occlusion of less than 15 seconds is an indication for the use of an arterial bypass during the surgical procedure.

The practical clinical appraisal of patients with symptomatic arterial occlusive disease and the selection of cases for surgery based on this appraisal should be the pattern of surgical vascular indications in private practice. When a procedure offers a mechanically and technically good, but unnecessary functional result, it is probably not worth the attendant risk.

A good survey of the results of experimental vascular surgical procedures as presented in the March issue* is very worthwhile. From it one can learn of and choose to use such procedures as have been shown to be helpful. As ever a critical appraisal of clinical and laboratory reports is still very desirable.

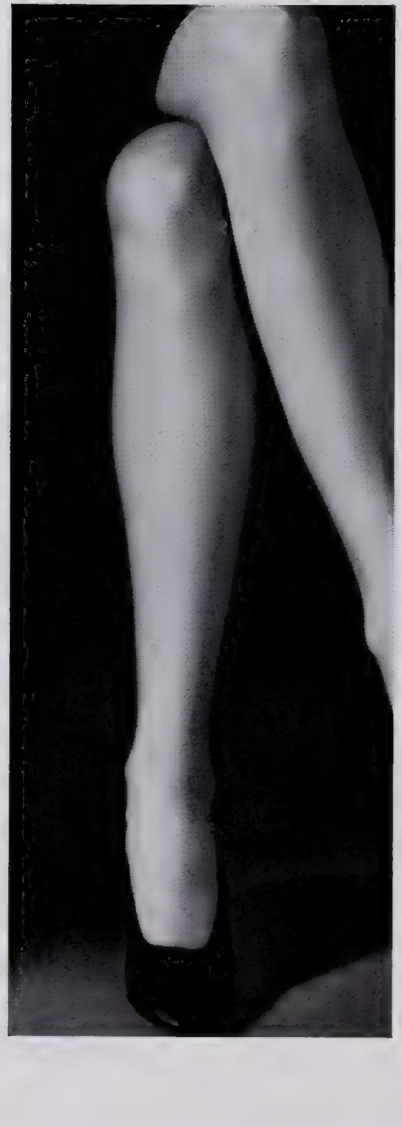
You prescribe elastic stockings. She won't wear them.

Now what?

Ultreer™



Elastic Stockings so sheer they look like support hose. Both Ultreer and support hose are sheer, shapely, cool and comfortable. But that's where the similarities end. New Ultreer fits firmly and evenly over the entire leg. Gives true therapeutic compression necessary to relieve varicose veins and other leg disorders. They provide the therapy you prescribe. The fashion and economy she demands.

Ultreer stockings have a new low price. So low, she can afford two pairs of Ultreer instead of one pair of regular elastic stockings. There'll be no disagreements there. Ultreer stockings are as comforting to her purse as they are to her legs. New Ultreer are the elastic stockings doctors and women can agree on.

BAUER & BLACK SUPPORTS DIVISION

Congenital Hip

IN EUROPE two orthopaedists — Von Rosen of Malmö[1] and Barlow of England[2] — have studied the hips of large numbers of infants from the time of birth to one year. Their work seems to indicate that one infant in sixty is born with instability of one or both hips. Apparently 60% of these become stable spontaneously in the first week of life as the effects of the hormone relaxin and of intrauterine position wear off. Almost 90% of these are stable spontaneously in two months.

In about one child in 650, however, the untreated hip remains dislocated beyond that time.

Management of a newborn with a dislocated or dislocatable hip is easy and successful, judging from what these men say. The hip, after being reduced manually, is simply splinted in abduction and flexion for a few months. The young socket, with its great growth potential, readily overcomes the incipient deformity.

In this country, however, the orthopaedist rarely sees a child with a dislocated hip before the age of walking. The diagnosis is commonly made first by a grandmother who notices a limp.

As the child grows older, the hip is less forgiving and less ready to improve. Prolonged traction is needed before reduction and prolonged splinting afterwards. By the age of one or two years, an open reduction is often required; as the child grows older this becomes more and more common. In older children whose acetabula have lost some of the potential for remodeling, surgery is sometimes necessary. Either the acetabulum can be moved over the femoral head by an osteotomy of the pelvis or reshaped by grafting its rim to make it deeper.

As a child with a congenital dislocation of the hip grows older, the results of treatment become progressively worse. They are so bad, in fact, that by the age of six the management of the problem is so unsuccessful that the deformity is often simply accepted. All of this unhappy and formidable treatment of older children apparently is avoidable if the hips of each newborn are examined carefully in the ways that Drs. Gustilo, Anderson and Cushing have described in this issue* and if the diseased hips are then promptly treated. In congenital dislocation of hips the golden opportunity is apparently gone when the child leaves the hospital undiagnosed.

Medicine teaches us to see men and shows them to us nearly always in a state of crisis. Birth, suffering and death, the infinite dramas that precede or follow these great events, those are the ordinary scenes of the physician. This is probably why so many writers have come from medicine or are products of a medical family. — Georges Duhamel (1844-   )

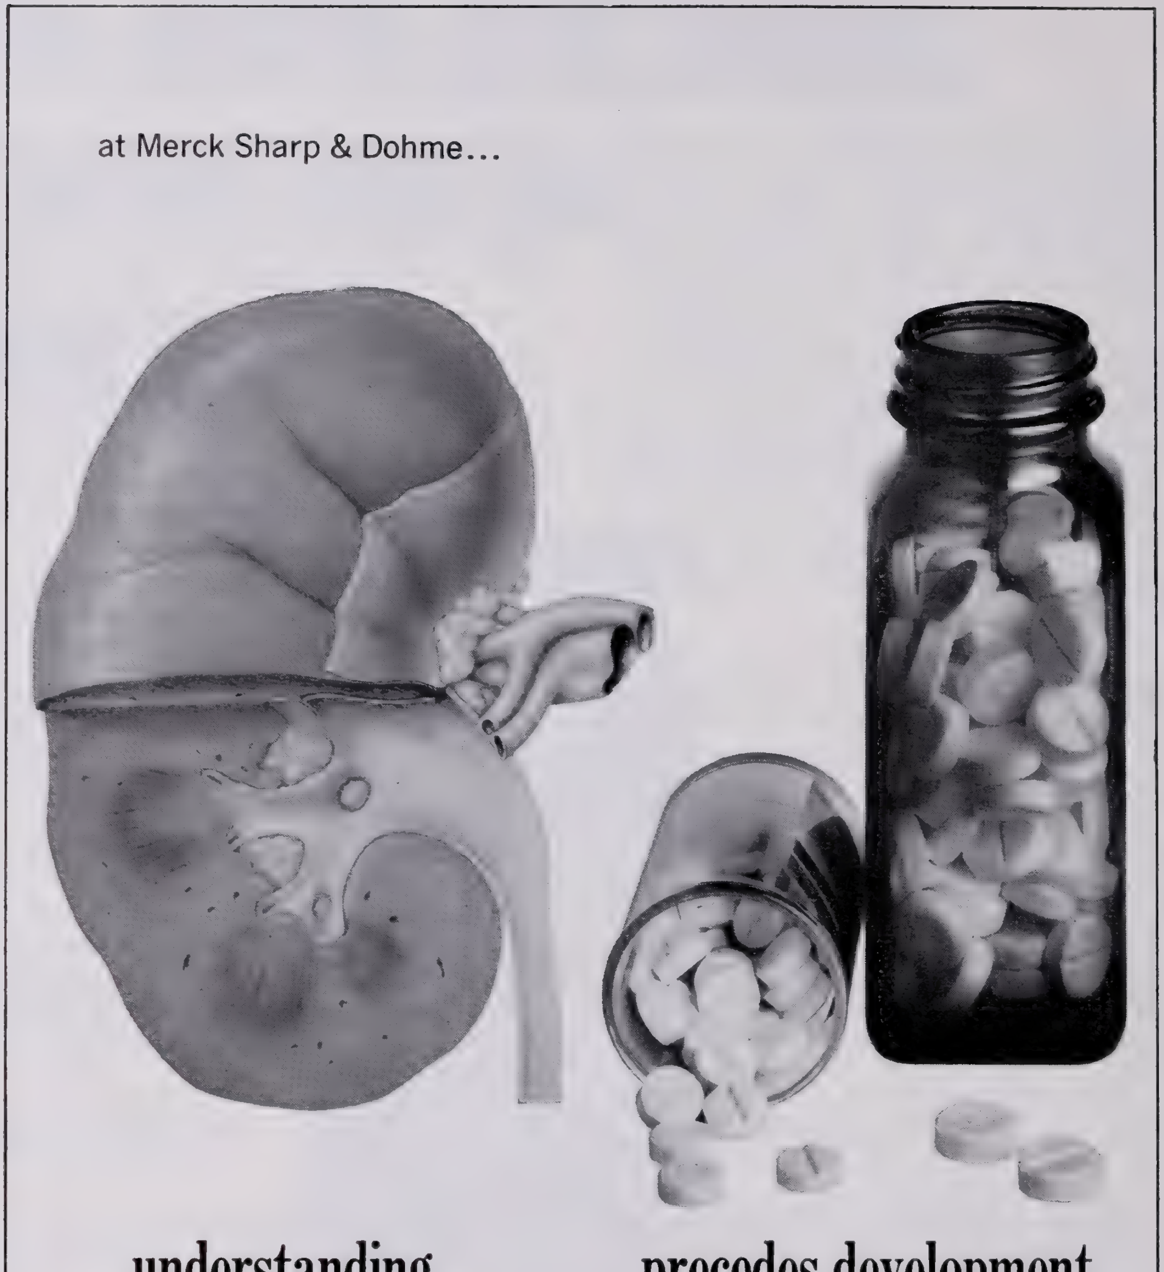
When men speak ill of thee, so live that nobody will believe them. — Plato



at Merck Sharp & Dohme...
understanding...
precedes development

The development of chlorothiazide and probenecid were events of major importance, but perhaps even more important for the future was the Renal Research Program by which they were developed. When Merck Sharp & Dohme organized this program in 1943, it was expressing in action some of its basic beliefs about research:

- Many problems connected with renal structure and function were still undefined or unsolved. The Renal Research Program would begin its basic research in some of these problem areas.
- From knowledge thus acquired might come clues to the development of new therapeutic agents of significant value to the physician.

For example, the Renal Research Program put fifteen years into this search before chlorothiazide became available. But because these years had first led to a greater understanding of basic problems, the desired criteria for chlorothiazide existed before the drug was developed.

Along with other research teams at Merck Sharp & Dohme, the Renal Research Program continues to add new understanding of basic problems—understanding which will lead to important new therapeutic agents.

where today's theory is tomorrow's therapy

Hypercalcemia

HYPERCALCEMIA IS mistakenly considered by many physicians to be rare and not life threatening. In the May issue, Doctors Flink, Desper, and Jones* present and discuss four cases of hyperparathyroidism seen during a 12-month period. One patient had an extremely high serum calcium level and died. The majority of patients with hypercalcemia from any cause see one or more physicians because of their symptoms and are followed for long periods of time before the hypercalcemia is recognized. Often extensive laboratory and x-ray examinations are made, but the serum calcium is not measured. These are the patients who progress to severe hypercalcemia and so-called "parathyroid or hypercalcemic crisis." The mortality in hypercalemic crisis is high, and those patients that survive may have permanently impaired kidney function.

The clinician must be continually on the alert to recognize hypercalcemia in its early stages. Hypercalcemia may be associated with a variety of diseases, the most common being malignancies, parathyroid adenomas, and vitamin D intoxication. The clinical manifestations of hypercalcemia are often quite striking but relatively nonspecific, and are, unfortunately, frequently attributed to other causes. Weakness, lethargy, coma, emotional lability, depression, constipation, leg pain, nausea and vomiting, excessive thirst and polyuria are the typical findings associated with hypercalcemia. The progression to severe hypercalcemia and crisis is usually not rapid, and the symptoms appear and become worse as the serum calcium levels increase. Serum calcium levels of 15 mg. % or higher are associated with severe symptoms and may result in hypercalcemic crisis with generalized precipitation of calcium in tissue, cardiac disturbances, and death. Few patients should progress to this stage unrecognized. Any patient with one or more of the above symptoms should have a serum calcium measurement. Patients who have renal calculi, malignancies, particularly those with bone metastases, sarcoid, multiple myeloma, duodenal ulcer, pancreatitis, long-term immobilization such as major fractures, and those patients taking vitamin D should have periodic serum calcium determinations.

As Dr. Flink and his associates point out, the medical management of primary hyperparathyroidism is generally unsatisfactory and not effective. With marked elevation of serum calcium, EDTA or citrate may have limited and transient benefit. These patients should have parathyroid surgery as soon as possible. Patients with hypercalcemia secondary to other diseases (neoplasm, sarcoid, myeloma, etc.) will usually show rapid and sustained decrease in serum calcium with adrenal corticosteroid therapy. These patients may have to remain on corticosteroids indefinitely in order to keep serum calcium levels normal or near normal. The hypercalcemia of primary hyperparathyroidism, in general, does not respond to corticosteroid administration.

The association of duodenal ulcer, pancreatitis, and renal calculi with primary hyperparathyroidism is well established. Patients with these three disorders are frequently seen in practice, and all should be screened for primary hyperparathyroidism by measuring serum calcium levels on two or three consecutive days. The reliability of measurements of serum calcium have been greatly improved with the newer EDTA methods, and even slight elevations become significant and make further diagnostic investigation mandatory.

Blueprint for dealing with tension due to stress — Prolixin — once-a-day

For the patient who must be on the job mentally as well as physically, prescribe Prolixin. The prolonged tranquilizing action of as little as one or two mg. helps him cope with tension all day long. Markedly low in toxicity and virtually free from usual sedative effects, Prolixin is effective in controlling both anxiety associated with somatic disorders and anxiety due to environmental or emotional stress. Patient acceptance is good — because Prolixin is low in cost, low in dosage and low in sedative activity. Prescribe Prolixin.

Side Effects, Precautions, Contraindications: As used for anxiety and tension, side effects are unlikely. Reversible extrapyramidal reactions may develop occasionally. In higher doses for psychotic disorders, patients may experience excessive drowsiness, visual blurring, dizziness, insomnia (rare), allergic skin reactions, nausea, anorexia, salivation, edema, perspiration, dry mouth, polyuria, hypotension. Jaundice has been exceedingly rare. Photosensitivity has not been reported. Blood dyscrasias occur with phenothiazines; routine blood counts are recommended. If symptoms of upper respiratory infection occur, discontinue the drug and institute appropriate treatment. Do not use epinephrine for hypotension which may appear in patients on large doses undergoing surgery. Effects of atropine may be potentiated. Do not use with high doses of hypnotics or in patients with subcortical brain damage. Use cautiously in convulsive disorders. **Available:** 1 mg. tablets. Bottles of 50 and 500. For full information, see Product Brief.

The Editor's Soliloquy

You May Be Right!

An idea may be conceived, but if it is unborn it can never maturate. Who of us has not had a seminal idea that we ignored and which later appeared full-flowered as the brainchild of someone else! Have we not then wished that we ourselves had been more aggressive in the promotion of that idea, instead of hesitating because of the risk of failure, the humiliation of being wrong, the fear of criticism, the dread of being derided as "too far out!" All of these inhibitions are unworthy of us. New ideas should galvanize — not paralyze us.

Progress depends on the conception, birth and maturation of new ideas. A so-called break-through is the terminal triumph of a revolutionary idea that germinated in the mind of someone perhaps no more capable than we but with more determination to "follow the gleam."

Humility is an admirable virtue — but not to the point of self-effacement: of sequestering oneself from the mainstream of progress and setting one's light under a bushel.*

People are naturally snoopy and love to read letters. London's NATURE magazine has thrived for years on letters to the editor. Through this medium numerous significant scientific advances have been initiated; likewise, other ideas have been discredited or rejected in the crucible of open forumship. MINNESOTA MEDICINE is your magazine, and though you may not have time to present us with a full, properly edited scientific manuscript, your ideas may prove valuable. Express yourself freely, spout off, let yourself go! We will do the editing.

In order to encourage your thoughts on any subject suitable for MINNESOTA MEDICINE, letters to the editor will appear under the heading "You May Be Right."** To this department for the presentation and cross-fertilization of ideas you are invited to contribute; though your name will be withheld if requested, your identity must be known. Ideas, observations, discoveries — even hunches; but no personalities! Be brief!

— Carl O. Rice, M.D.

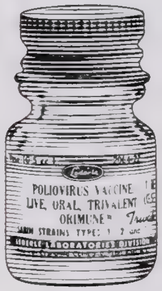
Doctor...two important Lederle products for routine office procedures

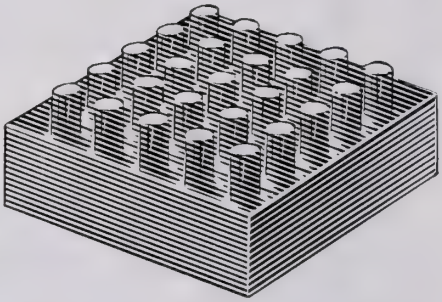


single-dose vials for convenient and economical polio immunization

ORIMUNE®
POLIOVIRUS VACCINE, LIVE, ORAL
TRIVALENT
SABIN STRAINS, TYPES 1, 2 and 3

Fast, simple administration—and economy for the patient — make the new 0.5 cc single-dose vial of ORIMUNE Trivalent ideal for private practice. (Packaged 5 to a box with 5 sterilized disposable droppers for your convenience).
(Also available in 2 cc and 2 drop dosage forms).
Only 2 doses required for complete, initial immunization for patients more than a year old.

Effectiveness—may be expected to confer active immunity against all three types of poliovirus infection in at least ninety percent of susceptibles only if given at full dosage, as directed. No characteristic side effects have been reported. There are, however, certain contraindications. These are, broadly: acute illness, conditions which may adversely affect immune response, and advanced debilitated states. In these, vaccination should be postponed until after recovery.
In infants vaccination should not be commenced before the sixth week of life. Do not give to patients with viral disease, or if there is persistent diarrhea or vomiting. ORIMUNE and live virus measles vaccine should be given separately.
Dosage—initial immunization: two doses each given orally at least 8 weeks apart. (Give a third dose to infants at 10-12 months). Booster immunization: one dose, given orally. See package literature for full directions.



simplifies routine screening

TUBERCULIN, TINE TEST
(Rosenthal) Lederle

Swab • Uncap • Press • Discard

Comparable in accuracy and reliability to older standard intradermal tests*, but faster and easier to use. Since TINE TEST is relatively painless it should receive greater patient acceptance. Results are read at 48-72 hours. The self-contained, completely disposable unit requires no refrigeration and is stable for two years.
Side effects are possible but rare: vesiculation, ulceration or necrosis at test site. Contraindications, none; but use with caution in active tuberculosis. Available in boxes of 5 (new individually-capped unit); cartons of 25.

You May Be Right

Is Therapeutic Abortion Natural?

As a practicing obstetrician, I feel I must take exception to the article Annotation on Life by Dr. Warren Warwick, in the December issue of Minnesota Medicine.

A favorable allusion was made to a "poignant" article in Life Magazine, June 4, 1965. However, no mention was made of the September 3 issue of Life, in which a two-column retraction appeared correcting certain errors and misrepresentations that appeared in the original article.

Dr. Warwick's attempt to logically prove that therapeutic abortion is "natural" is contingent upon the definition of "deformed" fetus. A deformed fetus may be a "major deformity incompatible with life," which is classically referred to as a blighted ovum, but this can hardly be equated with a fetus with a cataract or a clubbed foot.

Dr. Warwick's solution is purely pragmatic. This approach can be applied equally well to the deformed child and the deformed fetus. Applied to the newborn it will spare 50% to 90% of normal fetuses in cases of first trimester rubella.

Finally, I would question the advice to ignore the "dictates" of the clergy from an ethic that sees little difference between a human fetus and a normal appendix.*

St. Paul, Minnesota

Treatment of Malignant Tumors

After reading the work of Gallino and Grantham indicating that malignant tumors have a blood supply roughly twenty times greater than normal tissue and that central necrosis is a frequent occurrence in some human cancer, I have postulated that the treatment of malignant tumors by vasoconstricting drugs might cause sufficient ischemia to affect the growth of tumor cells without damaging normal tissue.

Accordingly, Angiotensin II, a vasoconstrictor drug, was used as the experimental drug.

Mammary adenocarcinoma was produced in three series of mice. The first series were untreated; the second series were treated with Angiotensin II after the tumors were palpable, and the third series were treated with Angiotensin II beginning at the time of implantation.

The series of untreated mice had a mean survival time of 90 days; the series treated with Angiotensin II after the tumors were palpable had a mean survival time of 109 days, and the series treated with Angiotensin II at the same time the tumors were implanted had a mean survival time of 93 days.

Is it possible that Angiotensin II is a factor in increasing the survival time in the second series?

John Brainard, M.D., M.S.

Annotation on Life

I do not believe the most important role of medicine is to prevent death and to preserve life. I do believe that the principal and important occupation of the physician is to campaign against ill health and disease which keep man, by physical or mental disability and suffering, from development of personality and fulfillment of life.

With these guides I attempted to consider the problem of therapeutic abortion for suspected congenital malformations, using rubella as a current, widely recognized cause of congenital malformations.

I tried to show that spontaneous abortion can be interpreted as an "efficient, beneficial and necessary," hence natural, "process by which defective fetuses" may be eliminated, and that under certain circumstances therapeutic abortions should be considered *just.* I suggested that the determination of *just* therapeutic abortions is a personal one to be decided by the parents and the physician, that they "consider carefully all the scientific facts available as well as the intangible doubts and dreads, and without hesitancy seek the counsel and advice — of minister, priest, or other physician." I counselled that they avoid the "dictate" of anyone who presupposes that black and white solutions apply to all the gradations of gray which exist between black and white. To so dictate is to assume the role of the Grand Inquisitor and to deny freedom to choose, to err, and thence to grow in ethical and spiritual strength.

My analogy to the operation for appendicitis was misunderstood. I acknowledged the comparison to be inadequate and hoped that its familiarity would prevent misinterpretation. One does not operate to remove a normal appendix (even General Eisenhower's elective appendectomy was for a suspected but quiescent problem) ; neither do I suggest here that therapeutic abortion be done to a normal fetus. The surgeon operates for suspected disease in the appendix, realizing that diagnosis is fallible; and in order not to miss an abnormal appendix he must at times operate on a patient who has a normal appendix.

Some abnormal fetuses survive to be born, even though most are eliminated by spontaneous abortion. I recognized and clearly pointed out that even under the worst of these circumstances some fetuses would escape rubella-induced malformations. My analogy was to the point that diagnosis of a malformed fetus is also fallible, that the risk of destroying a normal fetus must be considered and accepted in deciding on therapeutic abortion for a suspected malformed fetus. Therapeutic abortion is the "last resort" available to medicine to prevent the formation of a deformed child.

The birth of a deformed child is a focal point for the principal and important occupation of medicine — the relief of the child's disease to free him and his parents from the limitations imposed by that disease, so that he may have life more abundantly.

A pregnant woman's exposure to a teratogenic agent during the first trimester of pregnancy is another focal point. Physicians should be equally concerned about the parents and their freedom to plan for a family of "normal" children when, in the first trimester of a pregnancy, the probability becomes high that fetal congenital malformations are present.

I have not tried to dictate a solution to that dilemma. I have tried to present a logical argument to balance the prevalent one-sided authoritarian stand, so that the dilemma can be worked out by the persons involved.

Warren J. Warwick, M.D.
Minneapolis, Minnesota

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown®
(meprobamate)

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its antianxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of preexisting symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

Our Senior Educators

Fred L. Adair, M.D.

When a physician approaching the age of 90 years writes: "I do not know how much I deserve, but I have tried to do my best according to my lights," there is reason to explore at least a few of his major activities to determine what the physician who "tries to do his best" can accomplish.

Fred Adair was born in 1877 in Anamosa, Iowa, where his father, Lyman J., practiced medicine. At the age of 21 years Fred was granted the Bachelor of Science degree by the University of Minnesota and in 1901 the degree of Doctor of Medicine by Rush Medical College (University of Chicago). During the next two years he served an internship in the Michael Reese Hospital, Chicago.

In 1903 he began private general practice in Minneapolis, sharing office space with a group of physicians which included Dr. J. W. Bell of the University of Minnesota College of Medicine and Surgery. Concerning Dr. Bell, Dr. Adair recently wrote: "He was of great help to me in the early days and I did laboratory work for him to pay for office hours in his suite."

Continued

Dr. Adair was promptly invited to become a member of the College of Medicine and Surgery faculty, and his first work was in the dispensary at Seven Corners. His main interest was in pediatrics, but as there was no opening in that field, he did some work in internal medicine as well as in the laboratory.

During the year 1908-09 he did research work in Pathology under Robert Meyer in the Charite Hospital in Berlin where the world-famous Professor Ernest Bumm was the Geheimrath. On returning to Minneapolis, he limited his activities to obstetrics and gynecology, working in the first hospital on the College of Medicine and Surgery Campus, which was a converted residence on Washington Avenue "where we had a few maternity beds." He reorganized Home Delivery Service and later established prenatal clinics working with the local Infant Welfare Society and the Visiting Nurses Association.

Dr. Adair was invited to join the staff of the Minneapolis City Hospital (now Hennepin County General) where later he was elected Chief of the Department of Obstetrics and Gynecology.

When President Vincent reorganized the Medical School faculty in 1913 and all staff members were requested to submit their resignation, Dr. Adair was one of the 70 from 184 to be reappointed.

The Administrative Board of the Medical School was then composed of the Dean, Assistant Dean, and Heads of Departments. The members of the General Faculty wanted Board representation by a person who did not hold a headship. Therefore, on May 1, 1913, at a special meeting Dr. Adair was unanimously elected as its representative on the Administrative Board.

As a member of this Board, he was interested only in those activities which had to do with promotion of the welfare of the School. Other members of the Board had such complete confidence in Dr. Adair that he was appointed to membership or chairmanship of some of the most important committees. On July 2, 1914 a committee of five faculty members was appointed on teaching fellowships. To this committee Doctors C. M. Jackson and F. L. Adair were appointed permanent members. In 1915 Dr. Adair became chairman of the Committee on Appointments and Promotions of the Faculty. On September 13, 1915, he was appointed chairman of a committee to seek a new chief on a full-time basis for the Department of Internal Medicine. His committee recommended Dr. L. G. Rountree, who was appointed to the position.

In 1918 Dr. Adair's private practice was so large that he shared it with Dr. C. O. Maland who had graduated in medicine at the University of Minnesota in 1907, and who was not only an excellent physician but also a splendid co-worker. This arrangement allowed Dr. Adair more time for teaching, research, and organization activities.

The thesis Dr. Adair prepared while in Germany was acceptable to the American Gynecological Society to which he was elected to membership in 1915. Later he served as Treasurer and President of that Society. During World War I, Dr. Adair worked with the American Red Cross and established social and medical service in maternity hospitals in Paris and Belgium. The King of Belgium presented him with the Croix Civique for his work with the refugees.

In 1919 he was instrumental in originating the American Committee on Maternal Welfare, successor to the joint committee on Maternal Welfare, which in 1952 established the Fred Lyman Adair Foundation to raise funds for specific research and educational projects. Later he was elected to its Hall of Fame.

As a member of the American Association for Child Hygiene, Dr. Adair effected the formation of a joint committee for Maternal Welfare. During the Hoover administration he was appointed and served as Chairman of the Section on Prenatal and Maternal Care of the White House Conference of Child Health.

At the University of Minnesota Dr. Adair was promoted through the various positions of assistant, instructor, assistant professor, associate professor and professor of Obstetrics and Gynecology.

In 1928 he was invited to accept one of the highest positions in the land by the University of Chicago, namely, the Chairmanship of the Department and the Mary Campau Ryerson Professorship of Obstetrics and Gynecology. This also included the Chiefship of the staff at the Chicago Lying-In Hospital — a service known around the world. On October 3, 1929, the Board of Regents, University of Minnesota, accepted Dr. Adair's resignation and he moved to Chicago, where for 13 years he did excellent teaching, research, writing and administrative work.

He was one of the founders of the American Board of Obstetrics and Gynecology. After 10 years of service as Vice-President he resigned because of pressure of other duties.

In a book published by the University of Chicago entitled "Great Men," Dr. Adair was referred to as "four men in one": "first, a leader of the movement to extend prenatal and maternal care to every corner of the globe; second, a scholar with many contributions to almost every subject in the field; third, the organizer under whom the University of Chicago Department of Obstetrics and Gynecology produced such results as the discovery of ergonovine, the obstetric drug which reduces the danger of childbirth; and fourth, the obstetrician to whom fellow practitioners thousands of miles away have sent difficult cases."

Upon attaining the 65-year retirement age in 1942, Dr. Adair became Chief of the Division of Infant and Maternal Health in the Illinois Department of Health. He resigned during World War II to work with the War Food Administration for special needs in the Department of Agriculture with Dr. Russell M. Wilder.

In 1946 he was invited to give lectures on his specialty in Argentina, South America. He had previously been to Hawaii, also under the auspices of the U. S. Children's Bureau.

In 1911 Dr. Adair married Myrtle May Ingalls, who traced her ancestry back to the Mayflower. The tracing of his family tree, as well, stimulated their mutual interest in genetics, which eventually led to the formation of Adair Genetics Association, Inc. in Evanston, Illinois: "a non-profit organization devoted to giving aid and financial support to genetic research." The Adairs had three children.

The American Gynecological Society sponsored the Fred Lyman Adair Award to be granted for the best work of original quality related to human genetics. This award consists of a stipend of $2,000 plus a plaque given biannually, the funds furnished by the Adair Charities Incorporated, a corporation interested in improving mankind physically, intellectually, morally, and spiritually.

Continued

Dr. Adair has contributed many articles and produced several books in his field: one with Dr. Edith L. Potter entitled "Fetal and Neonatal Deaths." He was co-author of a book, "Obstetric Medicine," with E. J. Stieglitz. He also produced a two-volume work, "Obstetrics and Gynecology."

Many honors and awards have been showered upon him. In 1951, he was called back to Minnesota when, on behalf of the Board of Regents, President Morrill presented him with the Distinguished Service Award. In July 1959 he received the Gold Key from the Medical Alumni of the University of Chicago. As he was unable to attend the Alumni banquet, Dr. Edith L. Potter, Professor of Pathology at Lying-In Hospital, accepted the award for him. She said, "We are honoring one of the world's great gentlemen and great scientists, a man who made us proud for all the world that he was on our faculty." She expressed regret at being denied the honor of presenting the key directly to this "great red-haired man with the bushy eyebrows and the magnificent smile."

The same week he received a silver-mounted gavel from the Chicago Gynecological Society, of which he was president in 1933.

Dr. Adair became General Chairman of the first American Congresses of Obstetrics and Gynecology and served in that capacity through 1952. After moving to Maitland, Florida, in 1950, one of his chief activities was promotion of the Congress and development of the International Federation of Gynecology and Obstetrics with headquarters in Geneva, Switzerland.

In 1954 he was one of two inaugural speakers at the International Congress held in Geneva, Switzerland. After that Congress, he helped organize the International Federation of Gynecology and Obstetrics on an international scale, the groundwork of which he had laid in 1950, when he was general chairman at the International Congress in New York City. He served as Treasurer of the International Federation of Gynecology and Obstetrics from 1954 to 1958. "The organization is now well established on an international level."

Since moving to Maitland, Dr. Adair has served on the planning and zoning committee and later on the town council for four years. His major hobby is reading prose literature by medical authors and stimulating interest in human genetics.

J. Arthur Myers, M.D.
Minneapolis, Minnesota

For Whom the Doctor Comes

It is not only for the sick man, it is for the sick man's friends that the Doctor comes. His presence is often as good for them as for the patient, and they long for him yet more eagerly. How we have all watched after him! what an emotion the thrill of his carriage-wheels in the street, and at length at the door, has made us feel! how we hang upon his words, and what a comfort we get from a smile or two, if he can vouchsafe that sunshine to lighten our darkness! . . . Over the patient in the fever, the wife expectant, the children unconscious, the Doctor stands as if he were Fate, the dispenser of life and death. . . . One can fancy how awful the responsibility must be to a conscientious man, how cruel the feeling that he has given the wrong remedy, or that it might have been possible to do better; how harassing the sympathy with survivors, if the case is unfortunate — how immense the delight of victory.

— William Makepeace Thackeray (1811-1863)

Curbstone Consultation

Nitrogen Mustard

QUESTION: What is the current status of nitrogen mustard in the treatment of Hodgkin's disease and how does it compare in effectiveness with the periwinkle alkaloids and corticosteroids?

ANSWER: The chief usefulness of alkylating agents (such as nitrogen mustard) in the treatment of Hodgkin's disease is for constitutional manifestations or when the disease has extended beyond the scope of irradiation. There is little doubt but that occasional patients respond to single or repeated courses of nitrogen mustard. Remissions so induced may last for many months or several years. However, statistical studies fail to reveal any prolongation of average life expectancy in Hodgkin's disease treated with alkylating agents.

A unique area of usefulness for nitrogen mustard is in its use for medical emergencies concerned with spinal cord compression and airway obstruction. There is generally a prompt regression of the pathologic process without the danger of swelling that would follow radiation therapy. In such cases the use of nitrogen mustard should be followed by a full course of local irradiation since the effects of the drug may be transitory.

The two periwinkle alkaloids receiving most active clinical trials are vinkaleukoblastine and vincristine. It is apparent that these drugs are active in Hodgkin's disease, but experience with them is still in the preliminary stage.

Use of corticosteroids should probably be deferred until the benefits to be derived from x-ray, alkylating agents and perhaps the periwinkle alkaloids have been fully exploited. An occasional patient, however, with severe hemolytic anemia, thrombocytopenia, or leukopenia may respond quite dramatically. During radiotherapy adrenocorticosteroids often find an area of usefulness in supporting the elements of a depressed bone marrow.

following infection

B and C vitamins are therapy: STRESSCAPS B and C vitamins in therapeutic amounts...help the body mobilize defenses during convalescence...aid response to primary therapy. The patient with a severe infection, and many others undergoing physiologic stress, may benefit from STRESSCAPS capsules.

Stresscaps®

Stress Formula Vitamins Lederle

FOR PROFESSIONAL RECOMMENDATION ONLY

Each capsule contains:

Vitamin B_1 (as Thiamine Mononitrate)	10 mg
Vitamin B_2 (Riboflavin)	10 mg
Vitamin B_6 (Pyridoxine HCl)	2 mg
Vitamin B_{12} Crystalline	4 mcgm
Vitamin C (Ascorbic Acid)	300 mg
Niacinamide	100 mg
Calcium Pantothenate	20 mg

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

The Viewing Box

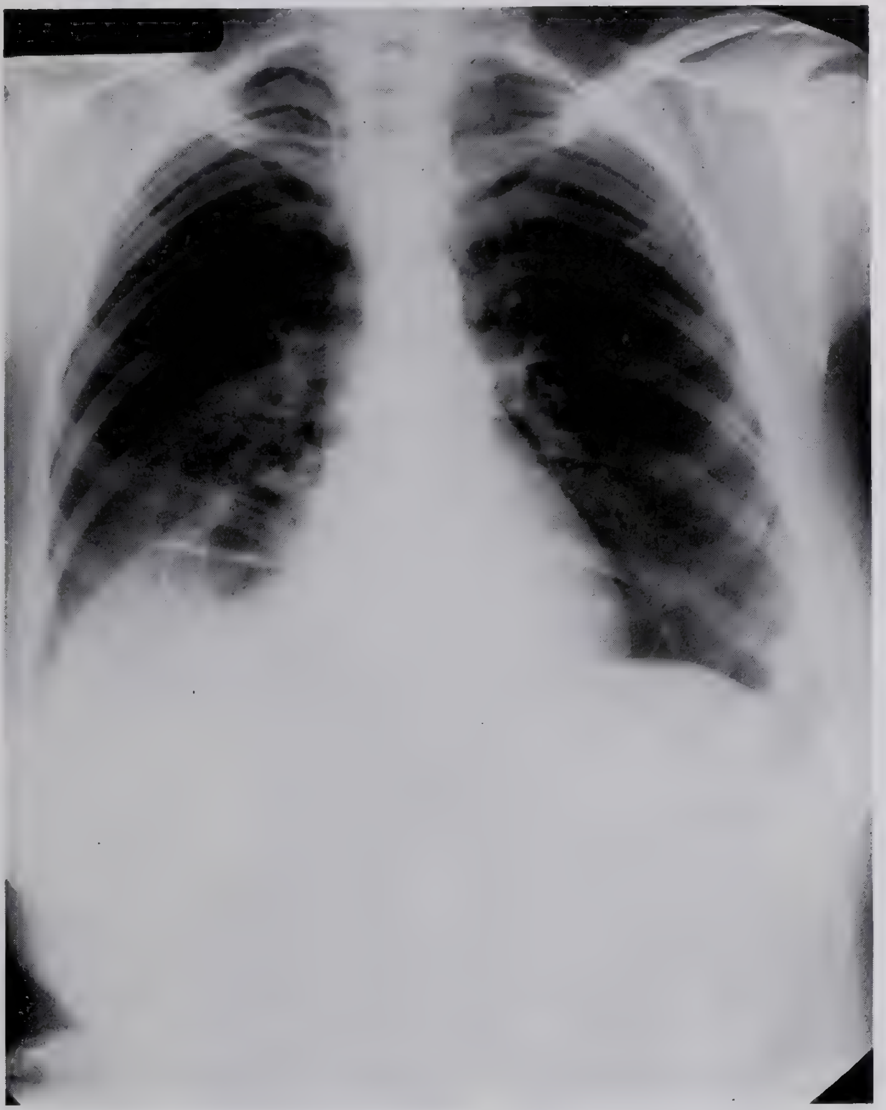

Figure 1

The patient was a 39-year-old woman who had been having attacks of high epigastric burning pain and vomiting for two years. The attacks lasted approximately 12 hours and occurred about once a month. She had noted easy satiation and experienced the need to belch constantly. Within the six months prior to her admission she had lost 60 pounds. Constipation had been a complaint for three months. The physical examination revealed nothing remarkable except for decreased breath sounds in the base of the right lung.

What is your diagnosis? (See next page)

Continued

Diagnosis: paraesophageal hernia

The posteroanterior thoracic roentgenogram (Figure 1) shows an irregular, lobulated shadow in the right paramediastinal area. This shadow corresponds to a portion of the transverse colon which has herniated into the thorax. The haustra are easily seen. This is further demonstrated in the roentgenograms made with contrast medium (Figure 2). During fluoroscopic examination the hernial sac intermittently contained almost all of the stomach, which appeared to be rotated to the right (Figure 3). The patient underwent surgical repair of the hernia which was of the paraesophageal type. The entire stomach and a major portion of the transverse colon were displaced into the sac of the hernia, located above the diaphragm. The diaphragmatic defect measured 7 to 8 cm. in diameter and was located between the two limbs of the right crus. The esophagogastric junction appeared in its normal position.

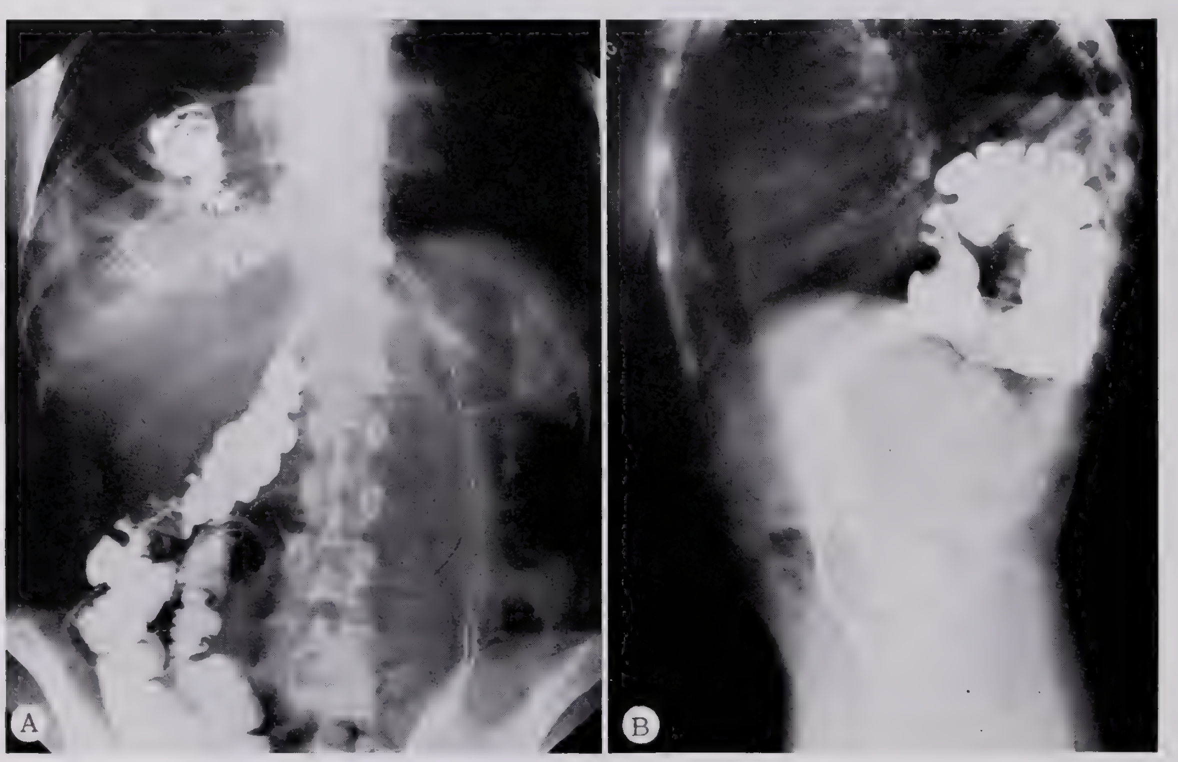

Figure 2

Paraesophageal hernias constitute about 5 to 7% of diaphragmatic hernias and are invariably located on the right side of the lower part of the esophagus. When the stomach enters the sac, it is usually malrotated with the greater curvature appearing on the right. These hernias are usually large and always lie in preformed sacs in contrast to the sliding hernias. In some cases the right hemidiaphragm appears poorly developed or is absent.

The shadow on the right base may be confused with a cyst or abscess or, if it does not exhibit gas, with a tumor. Sometimes, an important clue for the proper diagnosis is the lack of a gastric air bubble under the left hemidiaphragm. After the patient ingests barium suspension, the diagnosis becomes self-evident.

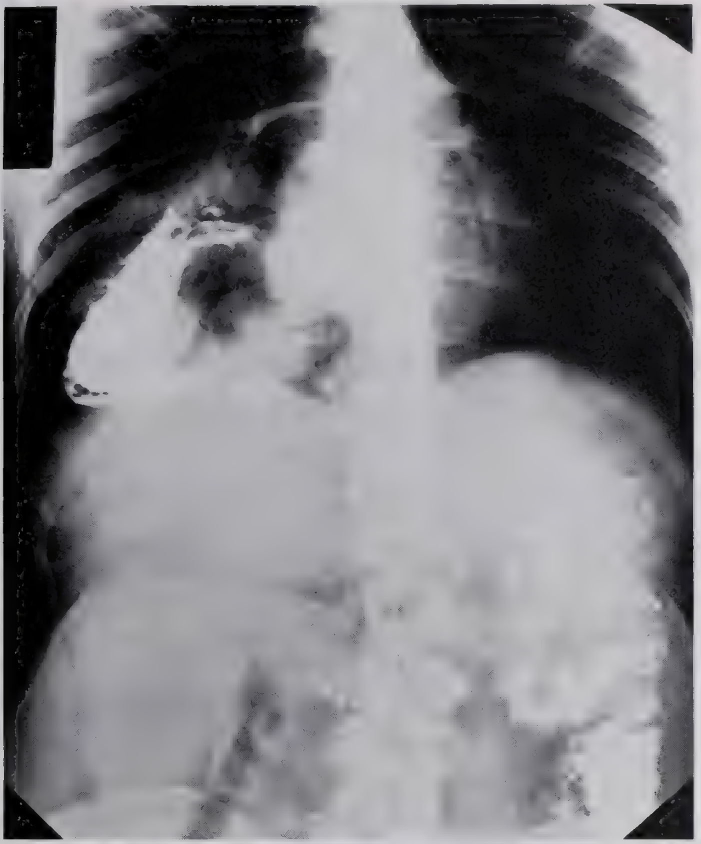

Figure 3

Barrett has offered an embryologic explanation for the occurrence of paraesophageal hernias. He considers the presence of the hernial sac to be due to persistence of the pneumatoenteric recess on the right side of the gullet. In his opinion, certain right-sided paraesophageal cysts have similar origin.

Since the cardia remains in its normal position with respect to the esophageal hiatus, esophagitis does not usually occur in this type of hernia. On the other hand, retrosternal discomfort after meals (sometimes simulating angina), obstruction due to incarceration of the hernia or volvulus of the stomach, and ulceration with hemorrhage and anemia may occur as complications. The treatment of paraesophageal hernia is surgical.

Fracture–Trauma Conference

Fractures of the Orbital Floor

IN MANAGEMENT of the facial trauma case the often subtle diagnostic clues to a fracture of the orbital floor may be overlooked. This is particularly true of the multiple-injury accident case in which attention is diverted to more immediate problems. The late sequelae of lack of treatment (enophthalmos, diplopia, and orbital-antral fistulas) are serious problems and can be avoided by appropriate early surgical intervention.

The following case history illustrates some of the findings in orbital floor fracture.

Case Report

A 27-year-old male was involved in an auto accident on 8-14-65 in which his face struck the windshield of his car. He was brought to Hennepin County General Hospital where examination revealed a confused, drowsy man with facial lacerations, bilateral

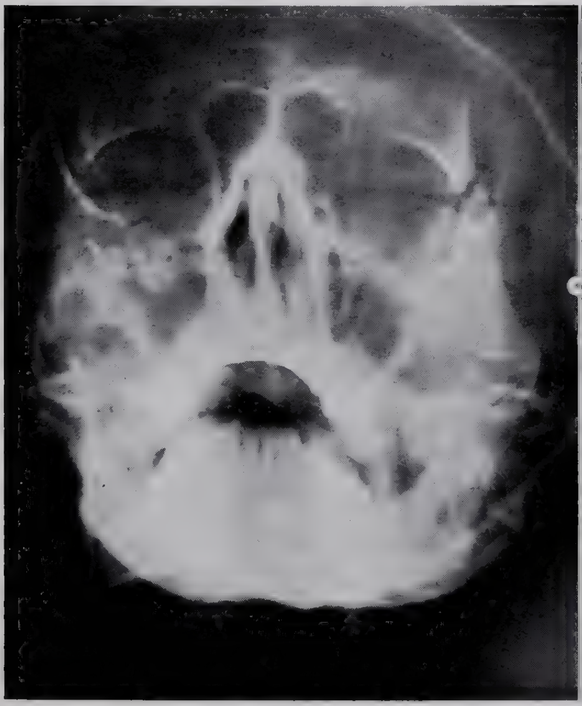

Figure 1-a

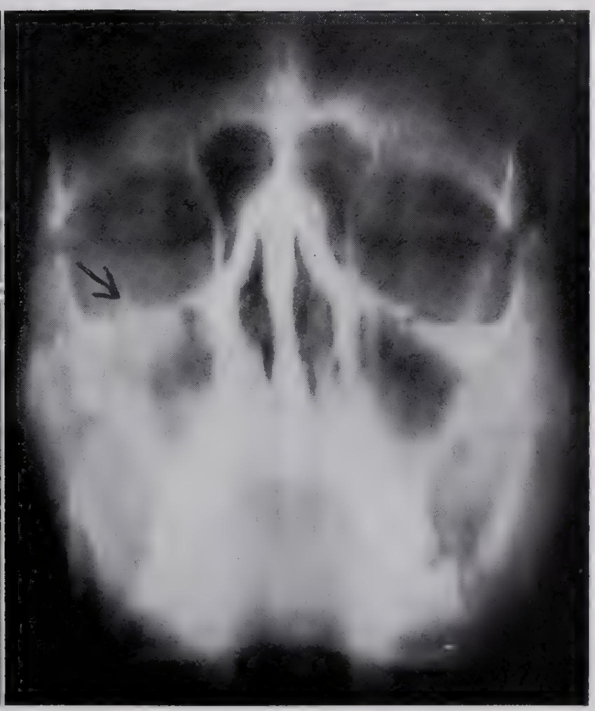

Figure 1-b

Continued

periorbital edema and ecchymosis, and subconjunctival hemorrhage. No other eye findings were noted on the initial examination. Roentgenograms demonstrated a right parietal skull fracture and bilateral frontozygomatic fractures.

The patient remained semicomatose for the ensuing three days, after which he became more alert and began to complain of double vision on upward gaze. Repeat examination revealed limitation of upward deviation of the right eye. Review of the x-rays was suggestive of an orbital floor fracture on the right (Figure 1a). Planigrams were obtained and demonstrated the fracture (Figure 1b).

The floor of the orbit was explored one week after the injury through an incision of the lower lid sulcus. An undisplaced fracture of the inferior orbital rim and comminution of the orbital floor were discovered. The inferior rectus muscle was freed from the floor fracture line and the floor elevated. The fragments locked into place, and the wound was closed. Postoperatively the patient was free from diplopia and made an uneventful recovery.

Discussion

This case demonstrates two of the four classic signs of orbital floor fracture: diplopia and x-ray evidence of fracture. These fractures are often seen on a routine Water's view and are usually well shown in AP planigrams. The diplopia is due to entrapment of or trauma to the inferior rectus or oblique muscles and is usually most obvious upon superior gaze. The dysfunction can be demonstrated with the traction test in which the eye is anesthetized with local Pontocaine, the rectus tendon is grasped with a forceps, and attempts at forced duction are carried out.

The third classic finding in floor fracture is enophthalmos due to loss of support of the globe. This, however, is often obscured by periorbital edema or depression of the orbital rim. The fourth finding is periorbital crepitance secondary to communication with the ethmoid or maxillary sinus. Other associated findings include a palpable step in the inferior rim, anesthesia or hypesthesia in the distribution of the inferior orbital nerve on the affected side, periorbital edema and ecchymosis, and subconjunctival hemorrhage.

If the possibility of an orbital floor fracture is kept in mind in the management of the patient with facial trauma, the diagnosis is usually readily made. Early surgical intervention can result in normal eye function and a good cosmetic result.

Neurological Conference

A Cerebrovascular Hemorrhage Due to Malformation*

Dr. Robert Soll

We have a case today of a young man, age 22, who had a cerebral hemorrhage resulting from a vascular malformation. In this condition about 70% of patients will present symptoms of either a spontaneous subarachnoid hemorrhage or a convulsion. Curiously, the most common cause of bleeding in teenagers and young adults is an arteriovenous malformation, whereas aneurysms are the most common cause in the older population.

History

While at work on June 22, 1965, this patient suddenly passed out during a coffee break. According to his wife he had had no previous history of seizures, nor had he complained of headaches or dizziness. Likewise, his general health had been good. Upon hospitalization in his home community, the patient was having major motor seizures. Examination at that time revealed fixed dilated pupils and bilaterally hyperactive reflexes and Babinski responses. On his third hospital day he developed pneumonia, which responded to chloromycetin and penicillin.

By July 8, 1965, the patient's condition had stabilized, although he was still semicomatose, responding only to deep pain. He was then transferred to the University Medical Center.

Physical Examination

Neurological examination at this hospital revealed an anisocoria,** the right pupil being larger than the left, and persisting hyperactive deep tendon reflexes of both upper and lower extremities with bilaterally positive Babinsky signs. His chest x-ray on the day following his arrival still showed a pneumonic infiltrate in the right lower lung. Films of the skull

Continued

were normal. A lumbar puncture revealed an opening pressure of 134 mm.H_2O and a closing pressure of 94. The spinal fluid was xanthochromic and contained one neutrophile, four monocytes and 11 red blood cells of which about one third were crenated. The spinal fluid protein was 56 mg%, and the colloidal gold curve had both a first and midzone elevation.

Gradually the patient's consciousness began to clear. Beginning the third week of July, he could obey verbal commands to turn his head, lift his arm, etc. About that time he was started on oral feedings. By mid-August he was able to sit in a chair, read, and tolerate a normal diet, although he was still too weak to walk. An almost complete expressive aphasia, a right central facial nerve paresis, and a paretic right hand and arm remained evident during his early convalescent period.

Carotid Angiogram

A left carotid angiogram was performed, presumably because of his right hemiparesis; but no abnormality was found. A right carotid angiogram revealed a satisfactory filling of the intracranial vessels. There was a moderate-sized arteriovenous malformation located in the posteroinferior aspect of the right frontal lobe bordering on, or possibly extending into, the parietal lobe just above the sylvian vessels deep in the sylvian fissure. This malformation is fed primarily by one major branch of the middle cerebral artery which is definitely enlarged as compared with the other middle cerebral vessels in this area. The branch apparently comes to the surface from the sylvian fissure and extends upward a short distance before it dips back into the substance of the brain to feed the malformation. There is a slight depression of the sylvian vessels just below the malformation, and there appears to be about a 2 1/2 mm. shift of the internal cerebral vein towards the left. This would suggest a hematoma in the area of the malformation. The circulation through the malformation is moderately fast. Elsewhere the vessels are normal.

Dr. Bill Bradley*

The patient has an abnormal electroencephalogram. We can't tell that he specifically has an arteriovenous malformation but we can say that he does have a lesion which is causing destruction of part of his frontal lobe. There is no epileptiform activity.

Dr. Soll

The question might be raised: why was a right-sided hemiparesis and right central facial paresis more apparent clinically, when the lesion itself was in the right hemisphere? The most likely explanation is the so-called crus phenomenon in which a supratentorial tumor may produce uncal herniation resulting in compression of the contralateral peduncle against the sharp edge of the tentorium. Ipsilateral paralysis, paresis, or reflex changes may then be found.

Dr. Frank Meelhuysen**

I examined the patient yesterday to determine the extent of his present functional incapacitation. While walking he doesn't clear his feet well, although he is not shuffling. He tends to lose his balance, falling toward the right side which apparently is weaker. When asked to walk on his toes and heels, he did quite well. He also keeps his head slightly tilted to the right with his shoulder elevated on the left. The Romberg test is negative. In checking his strength I found that it was almost equal bilaterally, but reduced. This can be attributed partly to deconditioning resulting from prolonged bed rest. Range of motion is preserved in all major joints of all four extremities. I have noticed that people who lie in bed for a long time develop tight hamstrings, and this patient manifests this on straight leg raising. His ankles could be flexed just beyond 90°. Slight incoordination of the right leg is evident during heel to knee testing; however, this is not as marked as his hand incoordination during finger to nose testing. Proprioceptive* loss is not apparent in the upper extremities, although it is minimally demonstrable in the toes.

*Assistant professor, department of neurology, University of Minnesota Hospitals.

**Assistant professor, physical medicine and rehabilitation, University of Minnesota Hospitals.

His wife mentioned that this man has difficulty in swallowing coarse foods such as meat. Liquids and soft foods can be handled quite well; but often he is afraid that he may choke. In view of this I checked his tongue motion and noticed that its movements are weak in all directions, and more so in tongue elevation. This can cause him difficulty in swallowing coarse foods because the tongue has to elevate to the roof of the mouth in order to move the bolus of food backward. There is a slurring of his speech, which can be accounted for by failure to make the right movements of his tongue. Dysdiadochokinesia of the tongue is present also, and there is a suggestion of tongue apraxia as well.

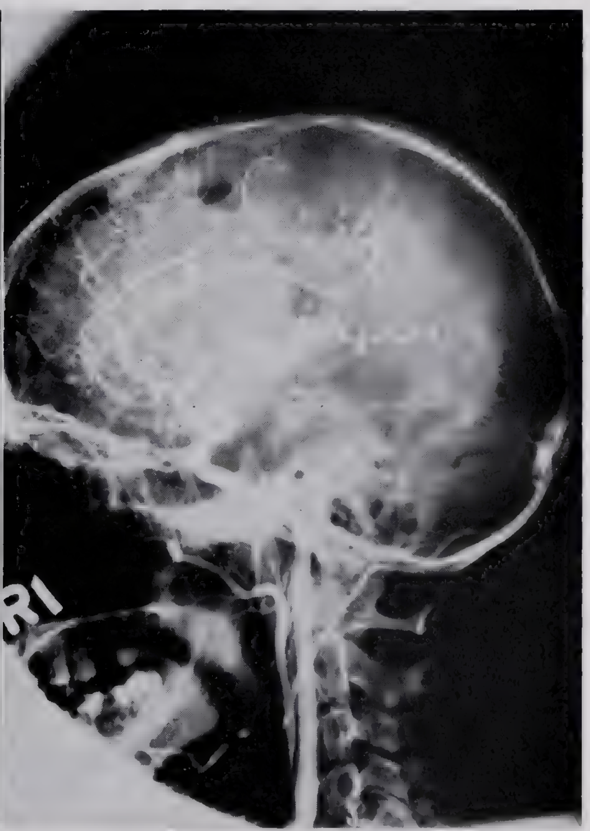

Fig. 2 — Right carotid angiogram showing surgical clips in region of the previously demonstrated A-V malformation.

Continued

Dr. David Danoff*

This lesion is in the right hemisphere which is probably the nondominant of the two hemispheres. A couple of facts that have to be considered are: first, there is a hematoma on the original angiogram which may account for his continuing weakness; and second, the vascular lesion is very likely still there. Occasionally a small malformation may bleed and subsequently destroy itself, causing no more trouble. The English have a large series of patients with subarachnoid hemorrhages upon whom nothing was found at the time of angiography and who have never bled again. They postulate, on the basis of autopsy reports on a few of these patients who finally did die, that they had had a small malformation which destroyed itself during the hemorrhage. This particular patient of ours, however, has what we call a giant malformation which would not be expected to destroy itself. We used to say that these things bleed repeatedly; that they are usually such small hemorrhages that a person may have a seizure or a headache and then get better; and finally, that until there was a definite loss of function, surgery was not necessary. In contrast, aneurysms produce a 50% mortality after the first hemorrhage; 50% of the remainder will bleed again in two weeks and 80% in a year. It is no longer felt that these lesions due to vascular malformation bleed repeatedly in a minor fashion, but rather that they are lethal or produce a moribund condition, as is the case with this patient. Since this lesion is in an area which is surgically accessible, it probably should be removed. In addition, the presence of a hematoma in this case would make the lesion more accessible, since it would establish a cleavage plane for the surgeon when enucleating the malformation.

Ligation of vessels may increase the degree of hemiparesis in this patient. When I saw him in clinic three weeks ago his hemiparesis was more profound than Dr. Meelhuysen has described it now, and I am surprised that he has improved this much. The presence of the hematoma may be causing part of his difficulty, and there is a distinct possibility that he may be stronger after its removal.

Mr. James Gilbertson**

The patient's verbal IQ is 80, his performance IQ is 65, and the full scale IQ is 72, placing him mentally in the moderately deficient range. Although he had average marks, he dropped out of school after the eleventh grade. I would estimate his premorbid intelligence to be around 95 to 100. The performance deficits suggest right-sided involvement. This is unfortunate for this patient because his strong areas before his illness were industrial arts and working with his hands. Now the presence of tremor and poor visual-motor integration make it almost totally impossible for him to do such performance tasks. Anything requiring speed or fast hand-eye coordination he is incapable of. Dr. Soll was interested in obtaining a baseline measure now, so that if an operation is done we can evaluate him afterwards to see if there has been any improvement. On the verbal tests I see no current evidence of aphasia. There is some loss of verbal skills, but performance and practical intelligence are most affected. He occasionally has some word-finding difficulties, but for the most part his communication is pretty good. His most noticeable speech problem is the dysarthria. The very low score on his Porteus test also suggests frontal lobe involvement. He is going to have trouble with vigilance, remaining alert, and making common sense decisions.

---

*Medical fellow neurosurgery, University of Minnesota Hospitals.

**Clinical psychology trainee, University of Minnesota Hospitals.

Dr. Meelhuysen

His wife mentioned that when he eats, he always finishes the left side of his plate first and has to be reminded several times to finish eating from the whole plate; so there might be a suggestion of visual field loss on the right side. I just wondered if you noticed this in his reading.

Mr. Gilbertson

I had him do some tasks; for example, there is one sub-test in the WAIS in which you have to pick out the missing parts, and he did fairly well on that. He also had to put together small pictures in order, nonverbal synthesis is what we call it, and he did fairly well on that too.

Mrs. Judy Edmands*

His oral reading was slurred, but he was getting all the words and there was no difficulty in rate or rhythm. Comprehension of silent reading was performed well with sentences but poorly with paragraphs.

Dr. James Story**

With all these findings I would still be concerned about a lesion in the left hemisphere. He may also have a field defect on the right. In addition, he is dysphasic and has a right hemiparesis.

Dr. Meelhuysen: He was originally classified as having total aphasia, but this is now reduced.

Dr. Soll

There was a very tiny anterior cerebral artery from the internal carotid to the mid-line which filled both anterior cerebrals as compression was applied to the right carotid artery. The remaining vessels appeared normal, however, and no contrast media passed over to the right middle cerebral.

Dr. Story

It is not uncommon to have an aneurysm associated with a malformation; also, the reason that the left anterior cerebral does not completely fill could be due to spasm related to an aneurysm. There is a configuration of the vessels on the right suggesting a hematoma but there is no appreciable shift. If you expect to explain everything on the basis of a crus phenomenon, I would expect more of a shift towards the opposite side; therefore I am somewhat disturbed by what I see.

Many of his signs and symptoms were suggestive of an aneurysm of the middle cerebral artery: the aphasia, the transient right hemiparesis, the visual field defect, and a little elevation of the left middle cerebral

---

*Department of audiology, University of Minnesota Hospitals.

*Assistant professor of neurosurgery, University of Minnesota Hospitals.

Continued

artery. The original conclusion on angiography was probably correct, but I am not entirely satisfied. In view of his clinical history I would do another left carotid angiogram before I tackled the malformation.

Dr. Meelhuysen: What is the incidence of vasospasm just after the onset of the subarachnoid bleeding? Could this account for the transient symptomatology that we see here on the opposite side?

Dr. Story

Vasospasm is very common. I think it is almost invariable. It could, account for the symptoms, but usually the vasospasm is most marked on the side of the aneurysm. In treating malformations surgically we have a number of criteria we go by: the presence of intractable seizures or intractable headaches would favor surgical intervention; a persistent or progressing neurological deficit might be construed as an indication for surgery; repeated hemorrhage is an obvious indication. As far as this particular lesion is concerned, I would recommend resecting it, since it looks as if it arises from the peripheral portion of the middle cerebral artery. It is a relatively small lesion, and as a result of the hemorrhage and hematoma a capsule around the lesion has probably formed. This encapsulation would make the removal a bit easier.

Student: How soon do you like to do surgery?

Dr. Story

As soon as the patient's condition permits, if the criteria or indications for doing it are present. This patient has a persistent neurological deficit and is probably going to bleed again.

Dr. Meelhuysen

Does the bleeding occur as a result of pressure; or what is the basic cause of bleeding in such a malformation?

Dr. Story: There is increased pressure within the veins, enhancing their tendency to bleed. Possibly straining will contribute to it, though hemorrhage can occur at any time.

Dr. Soll: What are the chances of doing this operation without producing a further neurological deficit?

Dr. Story: They are pretty good, especially in view of the severe hemorrhage he had with hematoma formation.

Miss Helen Kretchmer*

I talked to the patient, his mother, and his wife, and they are in complete accord with what has been suggested for his treatment. Both he and his wife come from large families. The educational level in his family is about to the sophomore or junior year in high school, indicating that they are probably in the lower range of average mentality. The father works in a feed plant in their home town. The mother is a cook in an all-night restaurant. The wife has been a waitress in the past and has done some babysitting up to the time the patient came home. They knew each other two and one-half years before they were married. There will be problems in the future for this young couple because of his great disability, but they do not complain. The family has been helping to support them. At the time he was in the hospital there was some question of initiating assistance from the welfare board.

---

*Supervisor and assistant professor social service, University of Minnesota Hospitals.

Dr. Story

Another consideration is the psychological problem, which can be difficult. If he has been advised that the malformation might bleed again, this can be a real handicap. We recently operated on an individual at the Veterans Administration Hospital who was an invalid from this standpoint. He has improved tremendously with the successful removal of his vascular malformation.

Dr. Soll

Many of these malformations are situated in the frontal lobe and for this reason may be prone to cause psychological disturbances. This is another common feature of vascular malformations. Dr. Story, would you do anything about surgery until after the termination of his wife's pregnancy, or would this have any bearing on planning his treatment?

Dr. Story: I don't think there is any great hurry. I don't know when the lesion will bleed; it could bleed today, I suppose, but my feeling is that I wouldn't be in any great rush about it.

Dr. Meelhuysen: When would you plan to repeat the angiogram?

Dr. Story: Just prior to operating on him.

The Patient Is Presented and Examined

Dr. Danoff: When we saw the patient in consultation in clinic he was unable to walk without assistance.

Dr. Story

He is still obviously and strikingly impaired mentation-wise, which makes me a little bit less eager to operate on him at this time. We probably would be able to remove the lesion without injuring him and thereby prevent him from having subsequent hemorrhage, but this is probably not going to help him in his over-all intellectual functioning.

Dr. Soll: It may be worthwhile to wait a few months and then repeat the psychological tests. My first inclination was to wait and possibly not even do surgery. You try to think about what you would do in your own case: whether you would want to live the rest of your life as a hemiparetic (a possible eventuality of surgery) or take the chance of bleeding again in order to be certain of retaining what function you have.

Dr. Story

I don't think the possibility of a paresis here is the big factor that is dissuading me. What makes me hesitant is his present intellectual incapacitation. Is he going to be a contributing individual; is he going to be

Continued

able to support his family; or is he going to be a burden to his family or the state?

Mr. Gilbertson

The most significant impairment for him right now is in practical functioning intelligence. Verbally he scores an IQ of 80, which isn't too bad, but it is lower than he was premorbidly. He has a 65 IQ on performance tests, which of course means that the only employment for him would be a simple task-oriented job. I would recommend waiting three months in order to obtain a significant re-evaluation psychologically. He has made rapid improvement to date, although I don't think he will keep improving at this rate.

Dr. Story: I think if he improved a great deal in the next two months, one would be inclined to be more vigorous with respect to surgical treatment.

Dr. Soll: If he doesn't improve, would you still be reluctant to operate; or under what circumstances of clinical change would you consider an operation?

Dr. Story

If he does not improve, I would not operate on him. If he should bleed again or develop uncontrollable seizures or progressive deficit, I would operate.

Mr. Gilbertson

He might do well in a really structured situation where he didn't have to do fine, coordinating-type work. He said he made furniture,—I don't know what that involves, but he doesn't seem to be impaired in gross motor activity of the very simple type. I don't know whether this disability will clear up or not, or whether he can be trained; but any job that demands speed, foresight or planning is beyond him at this time.

Dr. Meelhuysen

Recuperating from a vascular accident is slow, but the environment can be conducive to a patient's improvement. So when the mother, for instance, was so eager to help him with buttoning his shirt, I urged her to let him do it himself. Presently it takes him more time, but he is better off by helping himself. Another problem is his poor bladder control, particularly at night. Here again we have to teach the patient to go to the bathroom at more frequent intervals and to minimize fluid intake before retiring. Simple exercises can be demonstrated and taught to patients with incoordination. Some Frenkel's exercises for the legs, such as the heel to knee maneuver, are beneficial. For the upper extremities, a peg-board type of approach can be used in which one takes small objects out of a hole and replaces them. Finally, he should gradually participate in doing simple household activities. At present he does nothing; in fact, he is in bed most of the time.

Dr. Soll

In summary, we can recommend that he increase his activities in order to try to increase his functional ability at home. After two or three months we can repeat the psychological, neurological and physical medicine evaluation, following which another neurosurgical opinion can be obtained regarding surgery.

Robert Soll, M.D.
University of Minnesota

Addendum

The patient was readmitted to the hospital approximately two months following the conference. A left carotid angiogram was repeated and showed no evidence of a lesion in the left hemisphere. Subsequently an intra-arterial injection of Amytal confirmed the presence of speech dominance in the left cerebral hemisphere. The patient then underwent a successful craniotomy and removal of the A-V malformation. Two months following surgery he began part-time employment.

Participating in the conference were Miss Helen Kretchmer, Supervisor and Assistant Professor Social Service; Mrs. Judy Edmands, Department of Audiology; Dr. James Story, Assistant Professor of Neurosurgery; Mr. James Gilbertson, Clinical Psychology Trainee; Dr. Frank Meelhuysen, Instructor, Physical Medicine and Rehabilitation; Dr. Bill Bradley, Assistant Professor Neurology; Dr. David Danoff, Medical Fellow Neurosurgery and Dr. Robert W. Soll, Neurologist.

The Tobacco Tyrant*

Armstrong finds that cigaret smoking contains 1 per cent of carbon monoxide, while quickly-smoked Havana cigar contains 5 per cent.

Dixon demonstrated that the blood in cigaret smokers may contain 5 per cent of carbon monoxide. He believes that the effects of cigaret smoking are chiefly due to carbon monoxide.

Gies, Kahn & Limerick say tobacco smoke also contains collidin, aldehydes and carbon monoxide.

Huchard speaks of nicotin as a cause of arteriosclerosis. He proved this experimentally by injection of nicotin into rabbits.

Furbringer regards nicotin as the most toxic substance in tobacco smoke. It varies in quantity, according to him, from 2 to 7 per cent. The fresher the tobacco, the richer is the distillation product of nicotin. He asserts that the smoke from a pipe is freer from nicotin than that of a cigaret, and that inhalation of smoke into the bronchi increases the absorption of nicotin eight times.

Cushney showed that experimental nicotin injection "disturbed cardiac rhythm mainly by a neurotropic influence upon the ganglionic terminations of the vagus and sympathetic nerves." There may, therefore, be two opposite effects, slowing or acceleration, depending on the preponderance and selective action on the two nerves.

To be continued.

E. O. Giere, M.D.**

Medical Seminar

Hearing Loss and Delayed Speech Development

Techniques for Evaluating Auditory Acuity of Infants and Young Children

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

KNOWLEDGE OF the techniques for evaluating auditory acuity in infants and young children is mandatory for those confronted with the task of diagnosing auditory disorders in this age group. Prompt detection and proper evaluation of such disorders are important, since delay augments frustration, propagates retardation, and hinders the vital education and rehabilitation of those afflicted.

The purpose of this paper is to outline the problems in the differential diagnosis of infants and young children with delayed speech development, impaired hearing, or both and to present the methods used in evaluating auditory acuity in these patients.

Differential Diagnosis

Perhaps the most frequent presenting symptom in a child with a communicative disorder is the parents' complaint that the development of speech has been delayed. The pronouncement that a child fails to speak solely because he cannot hear may indicate an erroneous or incomplete diagnosis, for the differential diagnosis of delayed speech development, failure to respond to auditory stimuli, or both, includes not only peripheral hearing loss but also aphasia, emotional disturbance, and mental retardation.

A rational approach to diagnosis, propounded by Myklebust,[1] includes taking a detailed history, assessing behavior, and considering the results of auditory testing. A complete history includes a search for those factors (Table) which might contribute to the etiology.

Frequently the history obtained during the pediatrician's and neurologist's examinations may quickly lead the examiner to the

Some Etiologic Factors Related to Hearing Loss and Delayed Speech Development

Hereditary	Prenatal	Natal	Immediately Postnatal	Infancy and Childhood
Familial deafness	Rubella in first trimester	Prematurity	Asphyxia neonatorum	Meningitis
	Rh incompatability	Lengthy labor	Jaundice	Measles
	Trauma	Type of delivery	Convulsions	Influenza
	Emotional disturbance	Difficulty of delivery	Apathy	Pneumonia
	Medication			Encephalitis

Continued

proper diagnosis. Since this is not always the case, the analysis of behavior becomes an integral part of the total evaluation of the child. Although behavior is a subject in itself, the salient features which characterize the child with a hearing loss, the mentally retarded child, the aphasic child, and the child with psychic deafness will be mentioned for the purpose of differential diagnosis.

Peripheral Loss of Hearing

If residual hearing is present, children with peripheral loss of hearing usually respond to loud sounds much more consistently than do those having the other disorders mentioned. Characteristically alert, these children compensate readily for their auditory handicap by using other sensory modalities. For example, they display a marked sensitivity to tactile and visual stimuli — in contrast to those who have aphasia, mental deficiency, or psychic deafness. Also, children having severe peripheral hearing impairment typically have a monotonous, nonmelodious vocal quality. The aforementioned characteristics may be muted by superimposed emotional disturbance or mental retardation.

Aphasia

This term implies that underlying brain damage is the cause of the speech disorder. Some authors contend that central damage alone does not produce a reduction of hearing acuity.[2] With auditory sensitivity intact, aphasic children may not vocalize because they are unable either to comprehend speech (sensory or receptive aphasia) or to store speech and to use language (motor or expressive aphasia). Youngsters with sensory aphasia, which is considered to be the more common form, are more likely to be misdiagnosed as having peripheral loss of hearing; patients having motor aphasia generally respond normally to auditory stimuli.

The aphasic child usually has some degree of incoordination and generally lags in motor development when compared with other children of his chronologic age. The compensatory function of other sensory modalities is perceptibly absent. Hyperactivity and distractibility dominate the behavior of aphasic children, while meaningless jargon of good tonal quality distinguishes their particular attempts to verbalize. These children actually use different sounds when referring to the same object. Despite the rampant bursts of jargon, the aphasic rarely gestures or vocalizes during play situations.

Psychic Deafness

A clue to this diagnosis may be revealed through a history of gradual withdrawal by the child after he has developed some verbal language. This may persist until he relinquishes both speech and auditory contact with the surrounding environment. There is, of course, as wide a spectrum of psychic pathology as there is of the severity of hearing impairment associated with peripheral hearing loss.

Autistic children may be completely mute in contrast to both aphasic children and those having peripheral loss of hearing; however, when they vocalize, autistic children usually have normal tonal quality. A high-intensity, low-frequency sound with its resultant pronounced tactile sensation often fails to evoke a response as it might in the peripherally deaf child. Some of these children with psychic deafness exhibit profound fear of sound. On the other hand, incongruous, subtle, indirect responses to faint sounds may be observed.

Behavior is often quite bizarre and distinctly devoid of emotion. Motor ability is usually rather good in contrast to that of aphasic and mentally retarded individuals.

Mental Deficiency

Mentally defective children cannot perform as well as normal children of the same chronologic age. One would then anticipate a history of delayed motor and emotional development. These children generally vocalize with a normal voice quality and employ gestures within the limits of their ability. Usually they respond to familiar environmental sounds, but failure to react to pure tones or conversation certainly does not make the diagnosis of peripheral deafness and exclude that of mental deficiency. Unlike that of children with psychic deafness, the behavior of mentally deficient children is not bizarre.

Techniques for Evaluating Auditory Acuity

Tests Applicable to Infants and Children to Three Years of Age

The conventional modes of evaluating adult auditory acuity are often unsuitable for infants, because infants frequently lack the cooperation and responsiveness required to adequately assess auditory capacity by these means. Therefore, one must employ pragmatic techniques, especially for infants having a high risk of deafness, such as those with a history of Rh incompatibility, maternal rubella in the first trimester of pregnancy, cerebral hypoxia (during labor or resulting from birth trauma), and familial hearing loss.

Some of these tests are gross at best, and the evidence obtained usually depends on observations of the infant's behavior when a test sound is produced. Perhaps one of the best-known gross-behavior responses is the palpebral reflex which has been well documented and employed by many.[3] These tests are not intended to measure the threshold of hearing but are used as screening devices.

The distraction technique depends on the Moro or startle response, such as crying, turning of the head and torso, and cessation of activity in response to a sound. Here various acoustic stimuli, such as the sound of wooden clackers, bells, rattles, and so forth are presented out of the baby's peripheral vision, and the startle response is observed and recorded. Reproducible test situations can be created when the noisemakers have been calibrated as to frequency and intensity and their sounds have been stored on tape.

Suzuki and co-workers[4] tested newborn infants with pure tones of high intensity and concluded that "the most serviceable aural responses in the newborn infant are (1) blinking, (2) jerking of the body, and (3) sudden deep inspiration, and that the use of these three responses in combination with each other as criteria of neonatal hearing may constitute the most effective and reliable method for clinical audiometry of newborn infants."

Again, the concept behind this type of gross testing of high-risk infants is to determine which of them need more accurate evaluation of auditory acuity at a later date. The parents should be advised that these early reports are only tentative impressions, for many examiners have dealt with the complex problems arising from premature "definitive" diagnosis.

Other techniques have been devised in an attempt to evaluate accurately the auditory acuity of infants and young children. These tests are essentially electrophysiologic procedures designed to measure the threshold of hearing in difficult cases. Three types of electrophysiologic procedures have been mentioned in the literature — namely, electrodermal audiometry, electroencephalographic audiometry, and cortical audiometry.

Electrodermal audiometry (EDA) (psychogalvanic skin resistance audiometry is the older term) was first clinically introduced by Bordley, Hardy, and Richter[5] in 1948. This technique is essentially based on the sympathetic nervous system response to a mild electric shock. Skin resistance as measured by a galvanometer is the unconditioned response to the unconditioned electric shock, while the pure tone is the conditioned stimulus. After several shock-pure tone presentations, changes in electric skin resistance compared to a known resistance occur as a response to the pure tones alone without a concomitant shock; hence, conditioning has occurred and an attempt is made to determine auditory thresholds.

The clinical applicability of this method may be seriously affected by extraneous physical movements, certain endocrine problems, electric interference, and various nonauditory stimuli. After being shocked, many patients become anxious, uncooperative, and quite negative. Despite these serious limitations, electrodermal audiometry may still have a role in the total evaluation of the infant and young child with a hearing disorder.

The second electrophysiologic method is

Continued

based on electroencephalographic changes to auditory stimuli. Marcus, Gibbs and Gibbs,[6] in 1949, first reported on the use of electroencephalography as a means of diagnosing hearing loss in very young children. Electroencephalographic audiometry is still essentially in the research and development stage. This test can be performed only on sleeping patients, but it does not require preconditioning. Electroencephalographic audiometry has been employed in the case of infants under 18 months of age, below which electrodermal audiology is normally limited by the infant's high skin resistance.

The decisive drawbacks to electroencephalographic audiometry are the difficulty in interpreting the response patterns to auditory stimuli and the fact that an accurate threshold cannot be determined.

The third and most recent electrophysiologic method for evaluating auditory acuity is termed cortical audiometry. Cody and Bickford,[7] in 1965, introduced cortical audiometry as an objective test for evaluating auditory acuity in man. Here sophisticated computer-averaging techniques are employed to record averaged, evoked, cortical responses to auditory stimuli. By this technique, the auditory acuity in the speech frequency range (500, 1,000, and 2,000 cps) can be accurately determined for each ear in the awake, naturally sleeping, or sedated infant.[8]

Cortical audiometry promises both a simplified answer to the interpretative problem which still vexes the proponents of electroencephalographic audiometry and an objective means of accurately evaluating auditory threshold levels in infants.

Tests Applicable to Preschool Children

For testing preschool children, a great deal of credit goes to Ewing and Ewing[9] of England, who have worked for years testing and evaluating infants and children with hearing problems. They shunned pure-tone audiometry for this age group and based their methods on common sounds of the home environment, such as the tinkle of a teaspoon against a cup. Some workers object to the use of noisemakers; for the information is nonspecific, and the child can be better evaluated through history, interview, and physical examination.

Perhaps the single most useful established method of evaluating preschool children is play audiometry.[10] This consists of a short period of conditioning with the child listening to tones at relatively intense levels. When the tone is presented, a specific play action must be accomplished by the child, such as putting a ball in a box. Interest is maintained by changing the objects and games which serve as a reward for having heard the sound. When earphones are rejected, the tones are presented from a loudspeaker.

Most children can be play-conditioned, and the few who are unconditionable usually have problems other than, or in addition to, their peripheral hearing impairment.

Numerous variations and innovations of play audiometry have appeared in the literature. Some innovations were constructed to capture and maintain the interest of the child being tested. The peep show of Dix and Hallpike[11] of England, applicable for three-year-olds, was the first of many modifications of conventional play audiometry.

Ordinarily all of these tests are useful for children from three to six years of age, and complete audiograms usually can be obtained. Most children tolerate the earphones and respond satisfactorily to the standard pure tones. The peep show and its variations are not necessary as a routine procedure, for good results usually are obtained through conventional play audiometry.

The play situation has also been used for the development of discrimination tests for children. Keaster's[12] technique is suitable for determining the speech threshold for children from three to six years of age.

The electrophysiologic tests also can be used quite effectively for children in the preschool age group. The efficacy of these techniques, especially of cortical audiometry, can be demonstrated when dealing with uncooperative children who present difficult problems of diagnosis and who cannot be adequately evaluated by conventional play audiometry.

Comment

Infants and children having delayed speech development, hearing disorders, or both can present a formidable problem of differential diagnosis. Early diagnosis is essential to avert an irreversible speech handicap and to ensure optimal results through rehabilitative measures. It is important to recognize that pathologic conditions other than peripheral hearing loss may be responsible for delayed development of speech. A rational team approach, including the talents of the pediatrician, neurologist, psychiatrist, audiologist, psychologist, and otolaryngologist, may be required to separate the aphasic, the autistic, or the mentally retarded child from the child having peripheral hearing loss.

The correct diagnosis can usually be made from history, physical examination, and assessment of behavioral symptomatology and the results of auditory testing. On occasion it may be necessary to reevaluate patients with difficult diagnostic problems at a later date. This is especially true when varying degrees of mental retardation and emotional disturbance are superimposed on a child with peripheral hearing loss. The exact nature and reason for delayed speech development may not be discovered in some instances even after the most thorough investigation.

Gross testing can effectively determine which infants need more accurate evaluation of auditory acuity in the future. Cortical audiometry promises to be an objective means of evaluating auditory threshold levels in infants. It can also be used to advantage for preschool children and in those cases where conventional play audiometry is either unrevealing or impractical.

Summary

The most frequent indication of loss of hearing in a child is delayed development of speech. The differential diagnosis chiefly involves (1) peripheral loss of hearing, in which the child characteristically is alert and compensates for his handicap by using other sensory modalities; (2) aphasia, in which the child usually has some degree of incoordination and lacks the ability to compensate with other sensory modalities; (3) psychic deafness, in which the child usually has developed some verbal language and then has abandoned it in a general withdrawal from the environment; and (4) mental deficiency, in which general development is retarded but tonal responses tend to be normal.

Gross testing of auditory function in infants provides information of screening value only. Startle responses to auditory stimuli are most often used in these tests. Electrophysiologic techniques have been devised in attempts to acquire more definitive information. Electrodermal audiometry is based on a conditioning procedure and is affected by many extraneous factors. Electroencephalographic audiometry presents problems of interpretation and can be used only on sleeping patients. Cortical audiometry employs computer-averaging techniques and can accurately determine auditory acuity in infants and young children.

Perhaps play audiometry is the best established method for evaluating preschool children. However, the electrophysiologic techniques may be useful, particularly in the examination of uncooperative children or those with difficult problems of diagnosis.

Heart Failure and Abdominal Pain

Case Report

A 55-year-old married white female was admitted to St. Barnabas Hospital on April 6, 1960, for evaluation for mitral commissurotomy. She had had known mitral stenosis for ten years and for five years had been treated with quinidine and digitoxin for auricular fibrillation and congestive heart failure. In early 1959 she had an episode of lower leg pain, and a saddle embolus was removed from the abdominal aorta at the iliac bifurcation. She was placed on long-term dicumarol and improved. In the next year she developed increasing shortness of breath, paroxysmal nocturnal dyspnea, and a fifteen to twenty-pound weight loss. She had experienced periodic epigastric pain for three months before admission. The pain occurred after meals, awakened her at night, and was occasionally associated with diarrhea. The pain always subsided spontaneously.

Physical Examination

The patient was a middle-aged dyspneic female. Her blood pressure was 120/76 and her pulse was 80 with an irregularly irregular rhythm. The heart was enlarged. A diastolic rumble, a loud apical first sound, and a diastolic blow over the sternum were heard. The right side of the chest did not expand, and diminished breath sounds were heard over the right lung. The right chest was dull to percussion. Abdominal examination disclosed no masses or tenderness. A well-healed appendectomy scar was present. Both lower extremities showed pitting edema. The admitting diagnosis was mitral stenosis with right pleural effusion.

Laboratory Data

Laboratory work on admission included a prothrombin time of 22.5 seconds, a hemoglobin of 14.9 gm.%, and a WBC of 15,000 with 85 PMNs, a sedimentation rate of 46 mm./hr., a normal urinalysis and normal electrolyte studies. The electrocardiogram was abnormal with a right bundle branch block and digitalis effect.

Course

On the first hospital day, 1400 cc. of clear fluid was removed from the right chest. It had a protein content of 3.3 gm.%, a specific gravity of 1.016, and contained no organisms on gram stain. A culture of the fluid showed no growth. Her respiratory symptoms improved, but she began to complain of mild epigastric pain and two to three watery stools a day. On April 10 she vomited and complained of severe abdominal pain localized to the epigastrium. The pain became generalized. The blood pressure was 200/70 and the pulse 30 to 50. Examination showed abdominal distention without bowel sounds. Repeat laboratory studies included a prothrombin time of 17.5 seconds, a transaminase of 25 units, a WBC of 21,000, and a hemoglobin of 18.0 gm.%. No amylase was done. A laparotomy was performed, but the patient did not improve. Her temperature rose to 105°. Her electrolytes included a sodium of 147 mEq/L, a chloride of 88 mEq/L, a carbon dioxide of 32 mEq/L, and a potassium of 5.3 mEq/L.

Continued

Her BUN was 42 mg.%, and her prothrombin time was 52 seconds. No bilirubin was done, but her skin was icteric. After three days in the hypotensive state maintained by levophed, she died on April 14.

Dr. Lyle Hay*

Dr. Mork, may we see the x-rays of the chest and abdomen?

Dr. Frank Mork, Jr.**

A P.A. film of the chest on April 6 shows cardiac enlargement with straightening of the left heart border (Figure 1). This is characteristic of mitral valvular disease. The pulmonary and vascular markings are prominent, but the lungs are not edematous. There is an increased density at the right base extending up along the right lateral chest wall, which indicates probable pleural fluid. A repeat P.A. chest film the following day shows reduction in the right pleural fluid with residual underlying parenchymal changes that could represent atelectasis. A focus of pneumonia or a pulmonary infarct cannot be excluded. Flat and upright films of the abdomen, taken on April 10, show distention of the small bowel in the mid and lower portions of the abdominal cavity (Figure 2). On the supine film there is a suspicious small air bubble which could be within an abscess cavity but more likely is air within the duodenal cap. I see no evidence of free intraperitoneal air or fluid within the abdomen. There are no masses. The films incidentally show calcifications which are probably renal calculi overlying both kidneys. One would have to obtain an intravenous pyelogram for better evaluation.

Discussion

Dr. Hay

First, I assume this patient has had rheumatic heart disease with subse-

---

*Director of Medical Education, Swedish and St. Barnabas Hospitals.
**Radiologist, St. Barnabas Hospital.

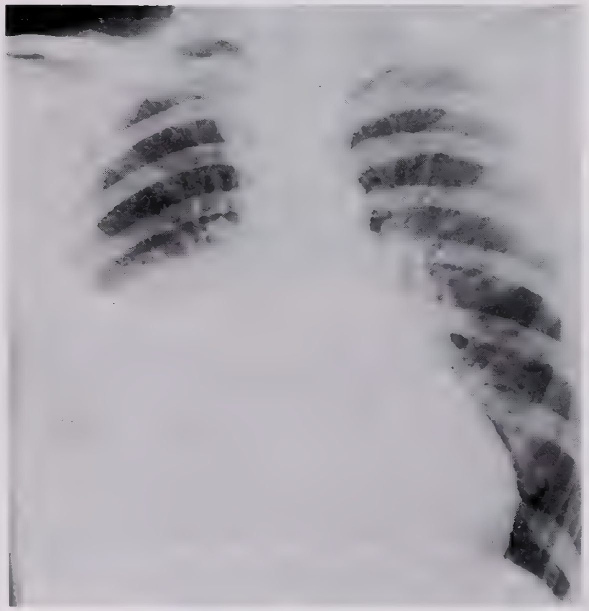

Fig. 1 — Film of chest taken on day of admission showing right pleural effusion and cardiac silhouette of mitral stenosis.

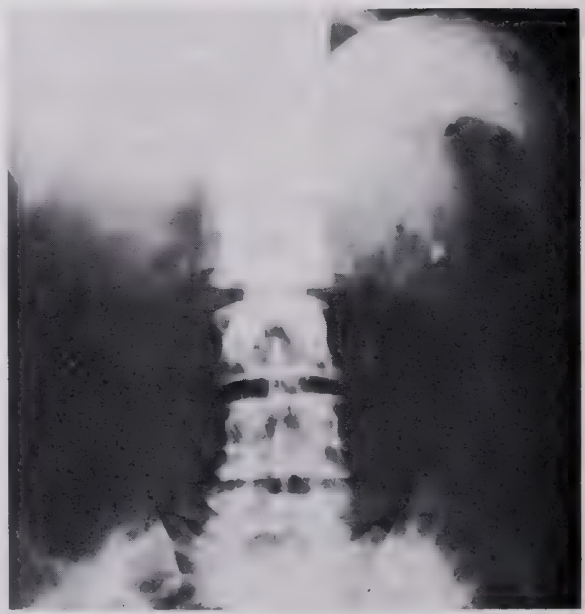

Fig. 2 — Abdominal film showing dilated small bowel loops. No masses or fluid are seen.

quent mitral and possibly aortic valvular lesions. She has dyspnea with auricular fibrillation and a history of an embolus. She is decompensated with secondary pleural effusion, which could be due to an abdominal condition. Patients with pancreatitis get pleural fluid, usually on the left side and related to abdominal effusion. Although pleural fluid can be seen on the films, abdominal fluid is absent. There is no increase in the liver to suggest a subphrenic process with pleural effusion. Whether or not she has had a pulmonary infarct is difficult to tell. It is more likely she has atelectasis from pleural effusion. The effusion fluid was a transudate because of the relatively low protein content and the specific gravity of 1.016.

Chronic Mesenteric Insufficiency

She has had epigastric pain which increased after meals and was accompanied by weight loss. This triad of symptoms has been ascribed to chronic mesenteric arterial insufficiency. I wonder if she has had an embolus to the mesenteric vessels with a partial occlusion. To be symptomatic, two of the three vessels that form the collateral blood supply to the intestine have to be closed. These vessels are the celiac axis, the superior mesenteric, and the inferior mesenteric. If only one vessel is gradually closed, collateral circulation will develop. Several times I have seen a large mesomesenteric artery coming up from the inferior mesenteric and entering the superior mesenteric just beyond its origin when there has been a block of the point of origin of the superior mesenteric from the aorta.

Pancreatitis

Pancreatitis should have been suspected when she complained of epigastric pain on April 19. She had nausea, vomiting, dull abdominal pain and dehydration. Hemoconcentration is common in pancreatitis. Her hemoglobin rose from 14.9 grams to 18 grams. This is certainly a reflection of hemoconcentration. She may have had an effusion into the peritoneal cavity, which we don't see, or she may have lost plasma into an organ such as the small bowel damaged from ischemia. If she had an edematous pancreatitis she could have had a retroperitoneal plasma loss. If she had a hemorrhagic pancreatitis, her transaminase would be elevated well above 25 units. Unfortunately, she did not have serum or urine amylase. This is unfortunate, because any patient who has an acute abdominal illness or catastrophe should have an amylase. In general, patients with pancreatitis should not be operated upon.

Mesenteric Thrombosis

In this patient with a history of mitral stenosis, with cardiac decompensation and previous history of an embolus to the aorta, the most likely abdominal catastrophe is an occlusion from an embolus. On the abdominal x-ray the small bowel is primarily affected. If the entire superior mesenteric artery is blocked, the ileocolic branch is usually blocked as well; and the right colon to the midtransverse colon is involved. I see no distention of the cecum or the hepatic flexure or transverse colon. The x-ray is not consistent with an ileocolic branch block, but this may be because the embolus has gone beyond the ileocolic vessel.

We weren't told whether this patient had fecal vomiting. She did have a

Continued

previous appendectomy; so a mechanical small bowel obstruction secondary to adhesions following the appendectomy cannot be excluded. We are told she had a silent abdomen. A silent abdomen is not characteristic of mechanical obstruction; so this must be a paralytic ileus.

I conclude that the most likely diagnosis in this patient would be a mesenteric embolus lodged beyond the ileocolic branch of the superior mesenteric artery, which accounted for her hypotension after the laparotomy and led to hemoconcentration. The rise in the white blood count from 15,000 to 21,000 is probably secondary to hemoconcentration. Other evidence for hemoconcentration is the elevated BUN and the electrolyte changes. Terminally she was in a hypotensive state maintained by levophed. I hope the clinician gave her levophed because he considered her to be in irreversible shock. In general, plasma or lactated Ringer's solution is better than vasopressers for patients with hypovolemia and hemoconcentration.

Jaundice

The presence of jaundice is a further indication of profound heart failure with increasing liver congestion. If you add hypotension and vasopressors as further insults to the liver, an increased serum bilirubin is a logical consequence. I doubt if jaundice means that she has gallstones or obstruction of her biliary tract, because obstruction of the bile ducts usually is accompanied by chills and fever — symptoms she lacked. I conclude she had a mesenteric infarction involving the small bowel. She may also have had a previous small embolus that gave her vascular ischemia and three months of abdominal symptoms. Finally, she had a rheumatic heart disease with mitral stenosis, decompensation, pleural effusion, and atelectasis with a possible pulmonary infarction.

Dr. Hay's Diagnosis

1. Mesenteric thrombosis possibly secondary to embolus, with infarction of small intestine.
2. Rheumatic heart disease with mitral stenosis.
3. Pleural effusion with atelectasis.

Comments

Dr. Wayne Chadbourn*

I was wondering if the patient had been on oral diuretics before admission.

Dr. Richard Reece

No, she received mercurial diuretics and had not been on Esidrix K.

Dr. Hay

I should have asked that question. Potassium in chlorthiazide diuretics has been established as a cause of small intestinal ulcers. This usually leads to the symptoms of a mechanical obstruction, not a silent abdomen.

Dr. Manuel Andrada**

His patient was on anticoagulant therapy. She might have bled into the bowel wall.

---

*Pathologist, St. Barnabas Hospital.

**Chief Resident in Surgery, St. Barnabas Hospital.

Dr. Hay

Hemorrhage into the bowel wall is a possibility, but again this would cause localized obstruction with cramps and high-pitched bowel sounds.

Dr. Mork:

The x-rays show no thickening of the bowel wall or mass. Both are usually seen with intramural hematomas from anticoagulants.

Dr. Alfredo Arriola*

We saw a patient last year with a similar history. The patient had a history of congestive heart failure and had been on dicumarol. She developed abdominal pain, and we diagnosed an embolus with mesenteric infarction. When she was explored, it turned out to be due to periarteritis nodosa.

Dr. Hay

Rheumatoid arthritis and periarteritis nodosa are both auto-immune diseases, but in long-standing rheumatic heart disease, an arteritis can usually be discounted. This patient had no evidence suggesting a smouldering connective tissue disorder.

Dr. Harsharan Kaur*

I have seen two patients with heart disease who suddenly went into shock. In both, levophed was given to maintain blood pressure, but both died. Each had infarction of the bowel wall without thrombi in the vessel. Could this be a similar patient?

Dr. Hay

There have been many cases where patients on levophed developed gangrene of the bowel.[1] The patient's own epinephrine causes vasoconstriction of splanchnic and peripheral vessels, and levophed increases the constriction. As experience accumulates in treating cardiac shock, the question is being raised if levophed is doing more harm than good. Although it dilates the coronaries, it increases the peripheral vascular resistances, thereby causing more work by the heart.

Dr. Angilito Ramos*

I found a report of operative cases with symptoms of heart failure although the preoperative diagnosis was mesenteric infarction but the vessels contained no clots at operation or autopsy. The authors attributed the necrosis of the intestines to mesenteric spasm.[2]

Dr. Andrada

If you suspect mesenteric embolism or thrombosis but are not sure of your diagnosis, when do you operate?

Dr. Hay

In a patient with mitral disease, such symptoms as abdominal pain with distention, paralytic ileus, bowel obstruction, vomiting, passage of blood either by vomitus or by stool, or hypotension are all indications for oper-

---

*Resident in Surgery, St. Barnabas Hospital.

Continued

ation. Laparotomy with a look at the intestine and palpation of the mesenteric vessels can save the patient's life. I had a resident who took out an elderly patient's appendix without looking at the remainder of the bowel or the vessels. The patient then died; he had an infarcted bowel. The resident then recalled that the bowel didn't bleed when he took out the appendix. Always look for the source of pain — don't do automatic surgery. It is better to find out whether it was a perforated ulcer, acute gallbladder, diverticulitis, twisted ovary, ruptured ovary, pancreatitis, or mesenteric block.

Pathological Discussion

Dr. Reece

We found a patchy, hemorrhagic necrosis of the stomach, duodenum, small bowel, and colon in the patient, and we believe it was secondary to heart failure. Hemorrhagic necrosis of the intestines is a common disease which has achieved popularity in the literature. In the last year seventy-five cases were reported from the Beth Israel Hospital in Boston, 31 cases from the Minneapolis Veterans Hospital, and 10 at the Lancaster Hospital in Lancaster, Pennsylvania.[3-5] In the report from the Beth Israel Hospital, Dr. Ming found 75 cases in 1535 consecutive autopsies — an incidence of nearly 5%. A review of this patient's lesions will illustrate the typical pathological picture.

The operation on April 10 was a small bowel resection. The provisional diagnosis before surgery was superior mesenteric embolism with infarction. As soon as he opened the abdomen the surgeon was confronted with a purple bowel distended with blood. The mesenteric vessels were collapsed but showed a feeble pulsation. The surgeon did not find a thrombus. He observed that the bowel wall bled briskly at all points where he cut into it. The pathologist, Dr. Chadbourn, described 16 feet of dusky hemorrhagic small bowel without any thrombi in the vessels. Microscopically, he saw an intact wall without any inflammation, but the mucosa showed hemorrhagic necrosis with extravasation of red cells in the lumen (Figures 3 and 4). No thrombi were found.

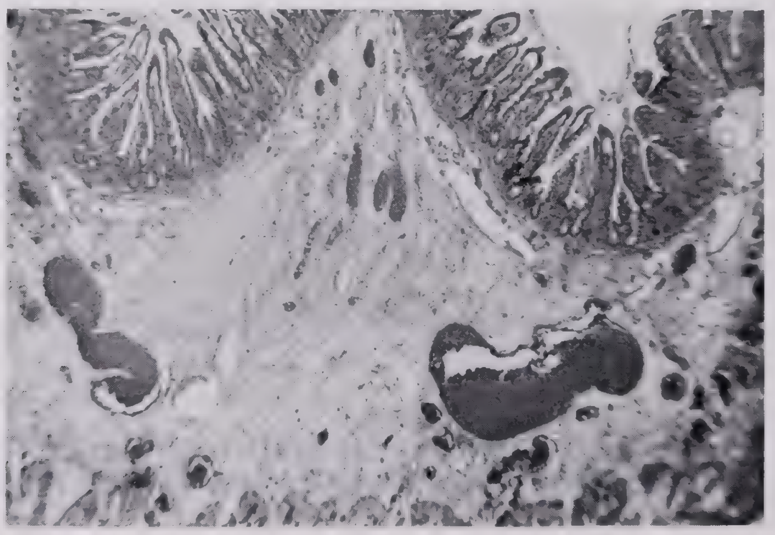

Fig. 3 — Photomicrograph of small intestine showing hemorrhagic necrosis of mucosa, edema of the submucosa, and dilated veins. (x35)

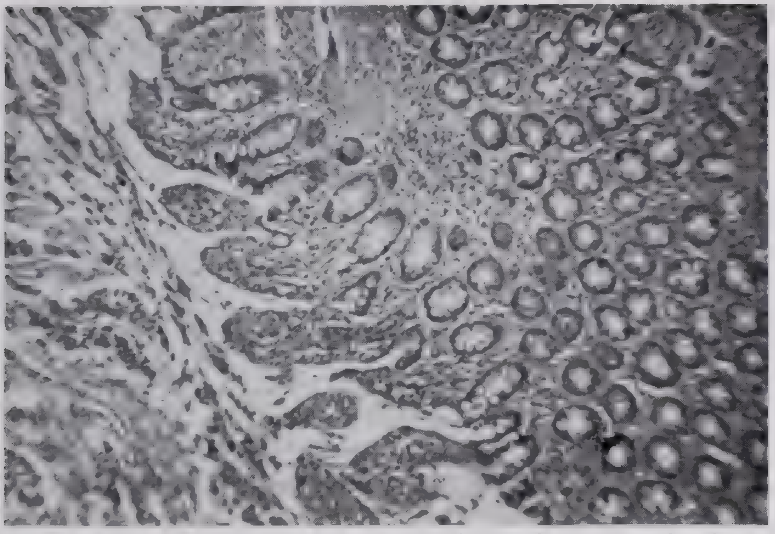

Fig. 4 — Photomicrograph of small bowel mucosa showing hemorrhagic villi and extravasation of red cells into the lumen. (x100)

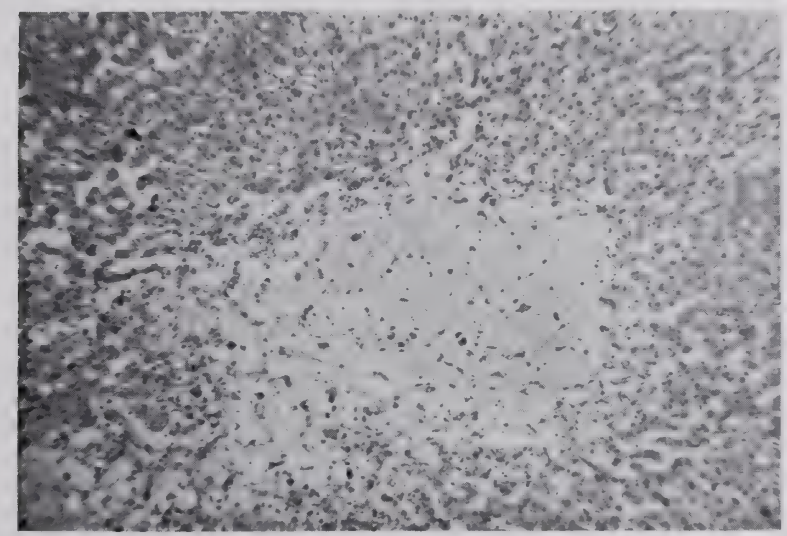

Fig. 5 — Photomicrograph of liver displaying extensive centrilobular necrosis. (x100)

Later at autopsy, the body was cyanotic and showed ankle edema and petechiae of the skin. The right pleural space was filled with hemorrhagic fluid. Both lungs were collapsed. The heart weighed 400 grams and showed a "fish-mouth" type of mitral valve, with large atria. There were no thrombi in the auricular appendages and no evidence of aortic insufficiency. The liver was mottled and showed severe centrilobular necrosis with neutrophils at the central zone (Figure 5). This probably accounts for her jaundice and her elevated prothrombin time because her liver was riddled with necrotic areas. The spleen was also enlarged and showed severe congestion and some early poorly demarcated infarcts with acute inflammatory reaction. The entire remaining gastrointestinal tract exhibited confluent hemorrhage of the mucosa.

Our final diagnoses were hemorrhagic necrosis of the gastrointestinal tract, rheumatic heart disease with mitral stenosis, and central hemorrhagic necrosis of the liver.

Continued

What is this disease complex of nonocclusive hemorrhagic necrosis of the bowel? First, a little history. In 1939 Penner and Burnham described 40 cases of necrosis in the bowel in which they found no thrombi.[6] Their paper was forgotten until 1954, when Wilson and Qualheim described 20 cases of a disorder simulating mesenteric infarction and occurring in individuals with chronic heart failure.[7] In the last six years a crescendo of reports have appeared,[2,8,9] and in the last year at least 116 cases have been reported of nonocclusive necrosis.[3-5]

Microscopically, changes are restricted to the mucosa, without necrosis or inflammation of the wall. The submucosal veins are distended with blood. Almost all patients have congestive heart failure, 80% are in shock, and 33% have gastrointestinal bleeding.[3] The common denominator in these patients seems to be a sharp decrease in the blood flow to the intestines secondary to vasospasm and with sludging in the splanchnic bed and venous distention. Digitalis toxicity increases failure and potentiates the syndrome.[9]

Signs and symptoms include abdominal distention, diffuse pain, vomiting, diarrhea, and decreased bowel sounds. In 60% of patients the symptoms last one day or less, but in the remainder the symptoms may be present for weeks or months.[3]

Dr. Hay

In animals with irreversible shock mucosal hemorrhage of the bowel is encountered. If the pancreatic duct is ligated to keep trypsin out of the lumen the animals tolerate more shock without an irreversible change. If antitrypsin agents are placed in the lumen of the bowel, a similar effect is achieved. Trypsin can be given either orally or by nasal tube.

Dr. Reece

A final comment on the chain of events. Patients in shock will perfuse their heart and brain to the exclusion of everything else. With profound heart failure intense spasm of all their mesenteric vessels results with shunting of the blood to the more vital centers. Because of the compensatory shunting mechanism, the bowel mucosa is deprived of blood and a conglomeration of microinfarcts results. The vessels of the small intestine, the arteries and the small bowel mucosa are extraordinarily vulnerable to anoxia.

Dr. Hay: This patient had heart block and marked systolic hypertension. Intestinal necrosis may have been the result of vasoconstriction in an attempt to save the vital organs.

Final Anatomical Diagnosis

Hemorrhagic necrosis of mucosa of gastrointestinal tract, patchy.

Centrilobular hepatic necrosis, severe.

Rheumatic heart disease, with mitral stenosis, visceral congestion, and right pleural effusion.

Grand Rounds

Nonocclusive Mesenteric Infarction of the Intestine

M. THOMAS STILLMAN, M.D.
Medical Resident

THERE ARE MANY causes of infarction of the intestine, among which are included mesenteric artery embolism or thrombosis, mesenteric vein thrombosis, and mechanical compression of these vessels or their branches. These causes may be grouped under occlusive vascular disease. There still remain the relatively few cases of intestinal infarction without demonstrable vascular occlusion. It is the purpose of this paper to present a case report to illustrate this phenomenon, discuss its varied aspects, and bring this entity to the attention of the clinician.

Clinical Syndrome

Many authors have reported various cases in which the bowel was implicated in the death of the patient. Marston[1] reviewed this subject and presented a useful diagram illustrating the various mechanisms of death in bowel ischemia (Figure 1). This paper will deal with that portion of the diagram leading to reduced mesenteric flow from nonocclusive or non-blocking mechanisms. It was not long ago that nonocclusive mesenteric infarction was first recognized as a definite clinical entity and referred to as pseudomembranous enterocolitis,[2] acute hemorrhagic enterocolitis,[3] acute hemorrhagic necrosis,[4] and hemorrhagic duodenitis.[5] The syndrome is now recognized as occurring in aged or chronically ill individuals with associated congestive heart failure, myocardial infarction, cardiac valvular lesions, and cardiac arrhythmias.

One of the first cases was reported in 1949,[6] that of a 73-year-old woman found to have a gangrenous small bowel without mesenteric vasculature occlusion. In 1951 Cohen[7] reported on a review of over 23,000 autopsy

Continued

studies and found four cases of infarction of the stomach secondary to vascular occlusion. An incidental finding of a case involving infarction of the entire large and small bowel with no vascular occlusion was mentioned in a patient with severe right heart failure. The first report of the clinical syndrome best fitting our case was that by Wilson and Qualheim in 1954.[3] They observed 20 cases, described this syndrome and its pathologic picture and differentiated the various types of nonocclusive ischemic bowel syndromes. In 1956 Wilson and Block,[8] and Jenson and Smith,[9] described studies of mesenteric infarction. Wilson reported six out of 32 cases and Jenson reported 10 out of 51 cases of infarction in which no occlusion was found at autopsy. Both pointed out that the occlusion, either an embolus or thrombus, was probably not found or dislodged at postmortem examination. In 1958 Ende[10] studied six cases and emphasized the importance of congestive failure as an etiologic possibility. In 1960 Ming and Levitan[4] reported on the pathologic findings of this syndrome, and Hoffman and others[11] pointed out the importance of cardiac valvular lesions as a possible etiologic factor. Since 1960 there have been other studies contributing to the recognition of this clinical entity.[12-19]

Incidence and Mortality

The reported incidence of nonocclusive mesenteric infarction varies. Two of the above studies reported a 20 per cent[8,9] incidence in which no occlusion was found in cases of mesenteric infarction. Berger and Byrne[12] reported on 110 autopsy cases of massive bowel infarction not including mechanical disturbances such as volvulus, hernia, or intestinal obstruction. About 21 per cent of the cases showed no mesenteric vessel occlusion, and a review of these cases showed much similarity to our patient. Wilson and Qualheim[3] found an autopsy incidence of about 0.6 per cent in reviewing 3,400 autopsies of patients over 30 years of age in a six-year period. The incidence is probably even higher, for in addition to the occasional case

that recovers there are cases that do not go on to autopsy study.

Usually the disease is rapidly fatal. The average duration of life when the exact onset can be determined has been reported to be from one to five days.[3]

Diagnosis

This disorder is generally found in the elderly, chronically ill patient. Most studies report a mean age of about 70 years, and there does not seem to be a predominance of one sex over the other. A common associated condition is that of chronic cardiovascular disease manifested primarily as congestive heart failure. The type of cardiac disease varies. Wilson and Qualheim[3] report 20 cases of this syndrome with 85 per cent having chronic heart disease. The predominant type was arteriosclerotic and/or hypertensive heart disease (Table 1). The frequent occurrence of congestive heart

failure, either chronic or acute, is also demonstrated in this report. This is substantiated by its presence in 100 per cent of cases reported by Ende,[10] 70 per cent of the cases reported by Ming and Levitan,[4] 90 per cent of the cases reported by Berger and Byrne,[12] 75 per cent of the cases reported by Kligerman and Vidone.[18] Musa[17] reported on 31 cases of intestinal infarction without mesenteric vascular occlusion. About 50 per cent of his cases had atherosclerotic and/or hypertensive heart disease and 30 per cent had rheumatic heart disease (Table 2). A number of studies include the presence of valvular lesions, the most prominent being aortic insufficiency as in the case study. About 30 per cent of the patients reported by Musa[17] had aortic insufficiency (Table 3). Hoffman and others[11] reported five cases of intestinal infarction associated with aortic insufficiency, 80 per cent of these cases having a syphilitic etiology. Other studies demonstrate this association.[20] The presence of arrhythmias has been demonstrated in cases of nonocclusive infarction of the bowel.[21] The predominant type has been atrial fibrillation. Musa[17] found atrial fibrillation present in about 40 per cent of his cases (Table 4). The presence of new or old myocardial infarction ranged from about 20 to 30 per cent of the cases.[17,18] Finally the presence of shock was common to many of the reported cases, but its exact relationship to the onset of symptoms of infarction of the bowel is not easily determined.

Signs and Symptoms

The signs and symptoms are essentially non-specific with reference to the gastrointestinal tract. They include abdominal pain, tenderness, disten-

tion, diarrhea (sometimes bloody), and vomiting (sometimes bloody). Their frequency is presented in Table 1. The presence of bowel sounds is highly variable as is the degree of fever. Usually because of the association of heart disease and non-specificity of abdominal findings, the abdominal problem is minimized in evaluation of the patient.

Laboratory Findings

Although the laboratory findings are variable, there seem to be certain constant findings. A leukocytosis up to 25,000 WBC was a frequent finding. A hemoglobin greater than 13 grams was reported in 90 per cent of the cases of Ming and Levitan.[4] Musa[17] reported albuminuria present in more than 90 per cent of the cases. He also reported a BUN greater than 25 milligrams per cent in more than 60 per cent of the cases. The laboratory findings in our case are consistent with the above reported data. Except for the radiologic evidence of non-obstructive ileus, there are no definite x-ray signs. Berger and Byrne[12] suggest that the presence of dilated small and large bowel patterns with the absence of air beyond the mid-transverse colon may be a radiologic sign. The diagnosis is not easily made, as demonstrated by the relatively low incidence of correctly reported diagnoses prior to autopsy.

Pathology

In fact, it is primarily on a pathologic basis[3,4,18] that this entity is separated from other necrotic lesions of the bowel.

Continued

Gross

The gross findings include a wide distribution of lesions but are most frequently localized in the distal half of the small intestine and proximal half of the colon. Some cases include the entire intestine from pylorus to anus, as in our case. The serosal surface is dark, purplish, and appears congested, and the presence of a thickened wall is usually due to the submucosal layer. The lesions occur in patches or segments unrelated to a particular vascular pattern as seen in occlusive vascular infarction. The lumen is often filled with a dark, bloody fluid. No mesenteric vascular occlusion is evident (Table 5).

Microscopic

A constant microscopic pattern is present. The early picture is that of hemorrhagic mucosa with blunted or edematous villi that become necrotic at the ends. The mucosal and submucosal vessels are dilated and engorged. There is no inflammatory reaction present early in this process. Later, the above is present in a greater degree and the only evidence of inflammation is in the areas of mucosal ulceration. The distincitve features of the pathological picture include widespread, often patchy, necrotic and hemorrhagic lesions limited to the mucosa and submucosa with little or no inflammatory reaction present.

Pathogenesis

The pathogenesis of nonocclusive mesenteric infarction is difficult to determine and remains somewhat vague.

Congestive Heart Failure with Increased Venous Pressure

The presence of congestive heart failure has been offered as a cause for infarction of the bowel. Ende[10] reported on bowel infarction occurring in cases of congestive heart failure. The resulting increase in venous pressure and liver congestion was thought to be a precipitating factor. Selkurt and Johnson[22] studied the effects of increased portal venous pressure upon the mesenteric circulation, and they point out that because the venous drainage of the intestine passes through the liver, the blood volume of the intestine is dependent upon the vascular resistance of the liver. By measuring blood flow through the portal veins of dogs as well as measuring weights of intestine, they were able to show an increase in mesenteric arteriolar vascular resistance resulting from increases in portal venous pressure.

Local Vasoconstriction

By the use of denervation as well as adrenergic blocking agents, they[22] proposed the presence of a local reflex or a direct myogenic response of smooth muscle within blood vessels. Increased vascular intraluminal pressure leads to vasoconstriction and secondary bowel ischemia. Paul and others[23] reported the presence of venous dilatation, capillary engorgement and edema of the intestinal wall in reviewing 50 cases of congestive heart failure. They did not report any cases of frank infarction. Thus it has been concluded that congestive heart failure itself does not cause intestinal infarction, but the secondary liver congestion and probable resulting additional vasoconstriction of the vessels in the splanchnic bed cause enough ischemia to result in infarction.

Arrythmia

Since arrhythmias are often associated with this syndrome, they have been reported as a possible etiologic factor. Irving and Corday[24] showed in dogs the effect of arrhythmias on mesenteric blood flow. Atrial fibrillation, commonly present in patients with this disease entity, reduced the flow an average of 34 per cent, with prompt return of flow to normal upon cessation of the arrhythmia.

Shock

Shock has long been proposed as a possible etiology in nonocclusive bowel infarction. A basic concept proposed by Fishberg,[25] the theory of selective vasoconstriction and redistribution of blood, operates during clinical shock. Irving and Corday[24] point out that a large amount of blood within the mesenteric circulation may be shunted to more vital organs such as the brain or heart, this quantity representing about 15 per cent of the cardiac output. They refer to the mesenteric circulation as the "homeostatic watchdog of the systemic circulation." Corday and Williams[26] further demonstrate this preferential vascular treatment of the brain and heart with resultant ischemic changes in the intestine as response to shock and the use of vasopressor drugs in dogs. In a unique experiment involving the isolation of loops of bowel in dogs, Corday and others[27] were able to show that angiospasm of the arterioles within the intestinal wall was the responsible factor in producing ischemia occurring during hemorrhagic shock and during the use of vasopressor drugs. The authors propose that this is the mechanism for hemorrhagic necrosis reported as following myocardial infarction, cardiac arrhythmias, and congestive heart failure. Lillehei[28] discusses the intestinal factor in irreversible hemorrhagic shock. He demonstrated that by perfusion of the intestine during hemorrhagic shock in dogs, the animals recovered upon retransfusion. The non-perfused dogs went on to die following copious amounts of bloody diarrhea. At autopsy the bowel showed severe mucosal congestion and necrosis. Lillehei also showed that by use of Eck fistula dogs, portal congestion is not the direct cause of bowel lesions secondary to shock conditions. In Musa's series[17] clinical shock was present in about 50 per cent of the cases, and it preceded the abdominal pain in only about 30 per cent of the cases. He felt that in man, shock was a factor in bowel infarction only when pre-existing disease (mainly heart disease) was present.

Immunological Reaction

Another factor considered as etiologic is an immunological or hypersensitive reaction.[13,15,29,30] Levine[15] reported a case of intestinal infarction without the presence of heart disease and demonstrated similar lesions in the intestine of guinea pigs by injection of rabbit Forssman antisera. The mechanism proposed with that Forssman antigen on the endothelium of blood vessels served as a focus for an antigen-antibody reaction, resulting in endothelial damage with increased permeability leading to edema, stasis, hemorrhage, and necrosis of the bowel wall. The presence of necrotizing arteriolitis involving terminal mesenteric vessels has been reported.[30] These lesions are similar to those seen in collagen diseases. An arteritis secondary to high doses of vasoconstrictor agents has also been reported.[29]

Neurogenic

Palmero and others[31] demonstrated that denervation of the abdominal

Continued

viscera leads to improved mesenteric blood flow during shock, thus implicating a neurogenic etiology in infarcted bowel lesions, and also that endotoxins produce shock indirectly via the nervous system. These authors felt that endotoxin stimulates the sympathetic nervous system to excessive activity leading to damage of the reticular endothelial system and failure to detoxify the endotoxin. The presence of endotoxin can produce the lesion of hemorrhagic mucosal necrosis.

Other Factors

Gazes and others[16] showed with hemodynamic studies that digitalis exerts constrictive effects on the liver, resulting in portal splanchnic venous congestion and a possible mechanism for bowel infarction.

Before we leave the subject of pathogenesis, one more theory should be noted. Hoffman and others[11] discuss the law of La Place. This relates tension in the wall of a blood vessel to the size of the vessel and the pressure within. Smaller vessels have limited stability. As the pressure within a smaller vessel decreases, its tone within the walls increases to a point at which there is complete closure of the vessel. Thus there are critical closing pressures below which a small arteriole within the intestine will become unstable and close. This can lead to edema, hemorrhage, anoxia, and necrosis without thrombosis or embolization. This has been proposed as a mechanism in aortic insufficiency.

Differential Diagnosis

Clostridium Welchii and Pseudomembranous Enterocolitis

The clinician is faced with the differential diagnosis of an acute abdomen, except that the abdominal symptoms in this syndrome are initally mild and often overlooked. It is not until late in the course that the clinician recognizes the associated presence of possible intestinal pathology. One entity known as enteritis necroticans is an enterocolitis that also has an abrupt onset, blood diarrhea, early circulatory collapse, and rapid progression to death. It is thought to be due to a Clostridium welchii infection of the bowel.[32] Nonocclusive mesenteric infarction differs in that previously well individuals are usually not affected and a causative organism is not isolated. The pathologic picture differs in that there is a lack of inflammation with involvement of only the mucosa and submucosal layers in the infarction syndrome. The pathologic picture as well as the presence of hemorrhage separates this entity from the pseudomembranous enterocolitis seen postoperatively or following the use of broad-spectrum antibiotics.

Occlusive Infarction

The real difficulty arises in distinguishing nonocclusive infarction from occlusive infarction, and this is usually not resolved until the patient undergoes surgical exploration or is studied at autopsy. Glotzer and Shaw[21] point out the importance of recognition of the associated conditions with nonocclusive infarction syndrome referred to earlier in the paper. In a review of 31 cases of massive bowel infarction they found nine cases without vascular occlusion. In the nonocclusive group, atrial fibrillation and other major arrhythmias were present in 78 per cent of the cases as opposed to 47 per cent of the cases in the occlusive group. Congestive failure was present in 67 per cent of the cases of nonocclusive and only 31 per cent of the cases of occlusion.

Treatment

Supportive Care

There is very little available in the way of definitive treatment for this entity. The importance lies in its recognition and vigorous treatment of the precipitating or associated conditions such as cardiac arrhythmias or congestive heart failure. Supportive care includes intestinal intubation to reduce distention, and the use of intravenous fluids. Most authors recommend the use of antibiotics to reduce the number of endotoxin-producing bacteria. Berger and Byrne[12] reported the average survival time of patients receiving no antibiotics or only a single dose to be 3.2 days. Those given more than a single dose lived an average of 7.5 days after the onset of symptoms.

Splanchnic Block

An excessive amount of vasopressor agents should be used cautiously in view of the findings noted earlier in the paper. Laufman[33] reported the beneficial effect of injections of procaine hydrochloride into the mesentery of strangulated bowel along with intravenous use of papaverine. Periarterial sympathectomy and continuous splanchnic block have been used with markedly varying results. It is generally accepted that these patients represent poor surgical risks as they are unlikely to have a surgically correctable lesion. If frank infarction is not found, nothing definitive can be done; if infarction is present, multiple segment involvement makes resection difficult or not feasible.

Summary

The syndrome of nonocclusive mesenteric infarction of the intestine occurs in elderly chronically ill patients with associated conditions such as myocardial infarction, cardiac arrhythmias, cardiac valvular lesions, and congestive heart failure. The mortality rate is very high. The signs and symptoms may include abdominal pain, tenderness, and distention with bloody diarrhea or vomiting. Laboratory and x-ray findings are not specific and the diagnosis is seldom made early in the course of the disease. The pathologic picture has been described in detail and the distinctive features include widespread involvement with hemorrhagic non-inflammatory lesions limited to the mucosa and submucosal layers. Many possible etiologic factors have been discussed, the exact mechanism remaining obscure. The mesenteric circulation serves a homeostatic function in that it shunts blood to more vital organs during clinical shock, often at the expense of the gastrointestinal tract. The treatment is essentially supportive and the importance lies in early recognition of the disease entity along with adequate treatment of the associated conditions.

Case Report

History

A 70-year-old white male was admitted on 9/29/65 for evaluation of shortness of breath and abdominal pain. The patient had been resting at home when he became acutely dyspneic, cyanotic, and markedly diaphoretic. He noted some abdominal cramping associated with this episode. He did not lose consciousness. The past medical history was significant in that he was hospitalized five years prior to admission for a myocardial infarct. He was again hospitalized eight months prior to admission for acute congestive failure and was told he had valvular heart disease. He was maintained on a digitalis preparation and a thiazine diuretic. Except for increasing exertional dyspnea during the week prior to admission, he was doing quite well.

Continued

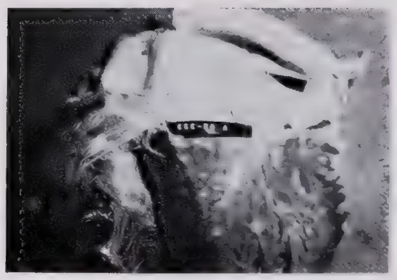

Fig. 1 — Stretched commissures of the aortic valve resulting in aortic insufficiency, high coronary ostia (pointer).

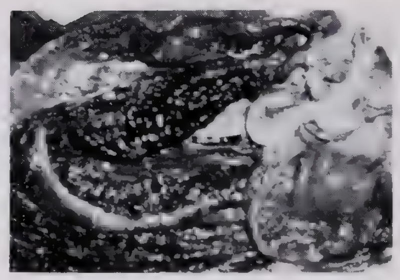

Fig. 2 — Congested, hemorrhagic infarcted bowel.

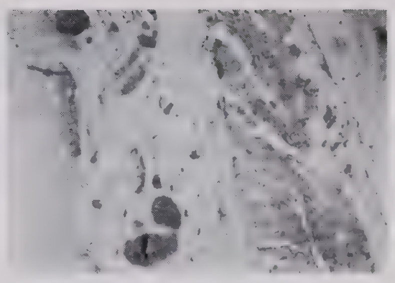

Fig. 3 — Necrotic mucosa, edematous submucosa with dilated vessels, minimal inflamation.

Physical Examination

The patient was an elderly man, cyanotic, dyspneic, diaphoretic, with moderate abdominal pain. Blood pressure was 180/90, pulse 120 and irregular. The presence of congestive failure was evident by distended neck veins, bilateral rales in the lungs, and a gallop rhythm. An apical systolic murmur and atrial fibrillation were present, but no diastolic murmur was detected. There was minimal abdominal tenderness upon palpation; there was no organomegaly; the bowel sounds were within normal limits and there was minimal pedal edema present.

Hospital Course

The initial EKG showed a rapid atrial fibrillation, left ventricular hypertrophy, and probable old anterolateral myocardial infarct. A chest film showed marked cardiomegaly. The patient's congestive failure responded well to increased digitalization, diet, diuretics, and bed rest; but on the second hospital day he developed increased abdominal pain, hypoactive bowel sounds, and grossly bloody diarrhea. Sigmoidoscopy was negative to 15 centimeters. Initial CBC showed a hemoglobin of 15.8 gm., WBC of 20,800 per cu. mm. with 91 per cent neutrophils, and hematocrit of 48 per cent. During hospitalization, the hemoglobin remained stable between 14 and 15 grams. The BUN rose from 52 to 89 mg. per cent. ESR rose from 1 to 26 mm. per hour, SGOT from 36 to 97 units. A serum amylase was 57 units. A sputum culture showed a mixture of organisms with E coli predominant. The patient was placed on penicillin and streptomycin. A blood culture was negative. The patient's bloody diarrhea persisted; he became febrile and progressively hypotensive, and died on the fourth hospital day.

Autopsy

The autopsy study revealed the following: the heart weighed 500 grams and there was a scar present in the anterior aspect of the lateral ventricle. There was a dilatation of the ascending aorta with stretching of the commissures of the aortic valve, resulting in aortic insufficiency. The liver showed acute and chronic passive congestion. Gross examination of the gastrointestinal tract revealed a purplish appearance of the entire ileum and large bowel which appeared congested, hemorrhagic, and infarcted. Microscopic examination of the intestine showed scattered mucosal hemorrhage and necrosis with minimal inflammation. The submucosa was edematous and dilated vessels were present. The mesenteric vessels showed *no occlusion.* The diagnosis was congestive heart failure and aortic insufficiency with secondary nonocclusive infarction of the intestinal tract.

Advances

Antibacterial Management of Infections Due to Gram-Negative Bacilli

Part II. Use of the Tetracyclines, Chloramphenicol, Polymyxin B, Colistin, Cycloserine, and Paromomycin*

WILLIAM J. MARTIN, M.D.**
Rochester, Minnesota

The Tetracyclines

INTRODUCTION OF tetracycline (Achromycin, Tetracyn, Panmycin KM, Polycycline) largely supplanted use of oxytetracycline (Terramycin) and chlortetracycline (Aureomycin), but the three agents are interchangeable for clinical use. Demethylchlortetracycline (Declomycin) is said to maintain higher blood levels longer than do the older drugs, but this is disputed. Pyrrolidinomethyl tetracycline or Rolitetracycline (Syntretin, Velacycline), when given by intramuscular injection, probably provides higher serum levels than the parent drug; the drug also can be given intravenously. There are other derivatives currently being investigated, such as 6-methyleneoxytetracycline, known as methacycline (Rondomycin) and given orally.

Indications for Use

As aforementioned, the tetracyclines along with streptomycin are used in such conditions as pneumonia due to *Klebsiella pneumoniae,* infection due to *Vibrio fetus* and brucellosis. In infections due to the tribe Mimeae a tetracycline along with kanamycin, polymyxin B, or colistin may be advisable. The tetracyclines are used, usually as single agents, in *actinomycosis, psittacosis, rickettsial diseases, pneumonia due to Mycoplasma pneumoniae,* and the less common venereal diseases: *lymphopathia venereum, granuloma inguinale, and chancroid.* In treponemal and gonococcal infections, the tetracyclines are useful in patients allergic to penicillin. In enteric amebiasis, the tetracyclines are used by some workers as adjuvants to other amebicides, but not in hepatic amebiasis. The tetracyclines are also used in patients with mucoviscidosis and other forms of chronic pulmonary disease. Favorable reports from tetracycline therapy are described in some cases of *Whipple's disease, tropical sprue, malabsorption associated with intestinal scleroderma, and diabetic diarrhea.* Tetracyclines are not used in infections due to beta-hemolytic streptococci or pneumococci unless in-vitro tests indicate susceptibility.

Side Effects

Nausea, vomiting, and looseness of the stools may occur on oral use of these drugs. However, when frank diarrhea results, staphylococcal enteritis should be excluded. Superinfection may be due to other organisms such as *Candida, Proteus,* and *Pseudomonas* and result in pneumonia, bacteremia, etc.

*See Part I Minnesota Med 49:835, 1966.

**Mayo Clinic and Mayo Foundation: Section of Medicine.

Drug fever, rashes, glossitis, stomatitis, and pruritus perenea are other untoward effects. Anaphylaxis, hematotoxicity, and pericarditis are rare toxic reactions.

When a tetracycline is added to solutions employed in peritoneal dialysis, the possibility of an untoward effect of the antibiotic should be considered. In markedly azotemic patients peak levels in serum, approaching the therapeutic range, may be reached within 24 hours.

The tetracyclines are not detectable in most normal tissues 12 to 24 hours after their administration is discontinued, but they may be retained indefinitely in mineralized tissues. Pigmentation and faulty enamel formation of children's teeth may follow use of the drugs either by the mother in late pregnancy or by the child in early life. Initially, the pigmentation is bright yellow but turns brownish with increasing age; exposure to light may intensify the pigmentation.

The tetracyclines are also retained in bone. If a tetracycline is given at a specific time before bone sampling, the amount of cortical bone formed between labeling and sampling can be measured by microfluorescence. The question has been raised whether deposition of the drugs in bones might inhibit their linear growth in premature infants, as has occurred in experimental animals. The drugs may be taken up by neoplastic bone and may have potential use in determining the level of amputation in osseous tumors.

Fluorescent Complex

Tetracyclines, excreted by the kidney and the hepatobiliary system, may be combined with calcium-containing urinary and biliary calculi to produce a fluorescent complex. Intermittent administration of a tetracycline to subjects prone to formation of urinary calculus may help determine the rate of growth of such stones, and also aid in evaluating regimens designed to prevent formation of calculi.

After prolonged tetracycline therapy, fluorescence of the nails may be demonstrable, and rarely can discoloration and onycholysis* be seen by the naked eye.

The affinity of tetracyclines for some types of malignant tissue, with fluorescence of the drug evident on exposure of the specimen to ultraviolet light, continues to be investigated in the hope that reliable diagnostic procedures will evolve. Patients given a tetracycline and then cystoscoped under ultraviolet light may be found to have malignancies of the urinary bladder, not evident on conventional cystoscopy. In the diagnosis of gastric carcinoma, testing of gastric washings for cells having tetracycline fluorescence may complement conventional cytology. Similar testing of duodenal fluid in patients suspected of having cancer of the pancreas or biliary tract is being investigated. Fluorescence may also help identify malignant cells in pleural and ascitic fluids. It is to be stressed, however, that these and allied procedures are largely investigational and that both false-positive and false-negative results are being encountered.

Accumulation in Damaged Tissue

In experimental animals, a tetracycline tends to accumulate in damaged but still viable myocardial tissue, particularly along the border of an infarcted area. In the living animal, a tetracycline tagged with iodine-131 is administered, and the radioactivity is measured via gammagraphy or scintillography. It is hoped that such investigation will lead to more precise identification of myocardial infarction in man.

Antianabolic Effects

The tetracyclines produce antianabolic effects that may have clinical significance in patients with reduced renal function. Negative nitrogen balance, increased urinary loss of such substances as sodium and riboflavin, increased azotemia, hyperphosphatemia, acidosis, and loss of weight may occur.

Hepatotoxicity

Fatal liver disease may occur in persons given excessive amounts of a tetracycline. Pregnancy, underlying hepatic disease, conjoint use of other hepatotoxic drugs, and impaired renal function increase the chances of hepatotoxicity. Most problems have resulted when more than 2 gm/day have been given intravenously, but the duration of therapy as well as the daily dose should be minimized when the drugs are given by any route. Jaundice, azotemia, acidosis, gastrointestinal bleeding, and hypotension may precede death. In doubtful cases, the serum concentration of the drug should be maintained at less than 15 μg/ml.

---

*See Test Your Word Score Page 943.

Photosensitivity, manifested by marked erythema and sometimes edema, is more often associated with demethylchlortetracycline therapy but has occurred after chlortetracycline, oxytetracycline, or tetracycline has been used.

A tetracycline, especially when administered intravenously, may interfere with blood coagulation; such findings as increased clotting time, decreased plasma prothrombin activity, lowered prothrombin consumption, and retarded thromboplastin generation may occur.

*Fanconi's Syndrome**

A reversible Fanconi's syndrome can result from ingestion of outdated or degraded tetracycline. Unexplained vomiting, dehydration, muscle weakness, polydipsia, polyuria, glycosuria with a normal blood sugar, or metabolic acidosis indicates the reaction; proteinuria, acetonuria, aminoaciduria, potassium depletion, and loss of calcium and phosphate also occur. Bence-Jones proteinuria has occurred. Aminoaciduria may persist after other alterations disappear. Lethargy may progress to coma. Gait disturbances may last several months. Packaging of the tetracyclines with alpha-lactose monohydrate may delay degradation of the drugs.

An isolated defect of renal tubular function, manifested by polyuria and hyposthenuria, following ingestion of demethylchlortetracycline has been described.[1] This example of so-called nephrogenic diabetes insipidus appears to be a reversible effect of the intact drug and unrelated to excessive dosage.

Increased Intracranial Pressure

With full therapeutic doses of a tetracycline in infants, increased intracranial pressure with bulging fontanels has been observed but has disappeared on cessation of treatment.

Dosage

In serious infections, 2 gm/day of a tetracycline are given orally in four divided doses; occasionally 3 gm. are given. As aforementioned, it is disputed whether smaller doses of demethylchlortetracycline suffice. A film-coated tablet of demethylchlortetracycline in amounts of 300 mg. has been marketed with the claim that, when taken every 12 hours, blood concentrations of the drug are similar to those after use of 150 mg. in an uncoated tablet every six hours. On an investigational basis, 150 mg. of methacycline has been given four times daily for as long as eight weeks. Concomitant administration of antacids and foods, especially those of a high calcium content, impairs gastrointestinal absorption.

Oxytetracycline or tetracycline in 100-mg. doses intramuscularly every six hours or 200 mg. every eight hours may be given. Also available is a preparation of oxytetracycline, which can be given intramuscularly in amounts of 250 mg. every 12 hours. As much as 500 mg. of chlortetracycline, oxytetracycline, or tetracycline can be given intravenously every eight to 12 hours. Rolitetracycline is given intravenously or intramuscularly in amounts of 250 mg. once or twice daily. The instillation of the tetracyclines into body cavities is to be avoided because of the irritating chemical properties of these drugs.

Chloramphenicol

Chloramphenicol (Chloromycetin) currently appears to remain the drug of choice against typhoid fever and is employed in certain staphylococcal infections and sometimes in infections due to Enterobacteriaceae. Because of its comparative ability to permeate the central nervous system, it is useful in selected cases of infection of the central nervous system, such as influenzal meningitis.

Continued

---

*See Minnesota Med 47:842, 1964.

Typhoid Fever

In cases of typhoid fever, a total of 45 gm. is given during a period of 14 days; some workers also give streptomycin for the first five days. Cortisone is given only to patients with severe pyrexia and toxicity. The 20% of patients who relapse are given a second course of chloramphenicol. The over-all mortality rate is less than 5%. As a generalization, chloramphenicol is not very effective in inducing permanent cures among chronic typhoid carriers; other drugs are often preferred.

Coincident with the declining rate of typhoid fever in the United States, an increase in other *Salmonella* infections has occurred. The natural habitat of these organisms is the gastrointestinal tract of animals and man, and the major sources of human infection are animals and their products, especially poultry and livestock. Many outbreaks occur after use of contaminated egg or egg products. Of the more than 800 known species of *Salmonella* organisms, the most common pathogen in human infection is *S. typhimurium*. Next, in decreasing order of frequency, are *S. thompson, S. newport, S. enteritidis,* and *S. heidelberg*. Clinical manifestations range from an asymptomatic carrier state to fulminating bacteremia; the latter cases are most commonly due to *S. choleraesuis*. Patients having certain underlying conditions such as sickle-cell disease, liver disease, and Hodgkin's disease may thereby be predisposed to *Salmonella* infection. Tetracycline, ampicillin, and other drugs may be more effective than chloramphenicol in systemic infections, and nonabsorbable agents like neomycin, kanamycin, paromomycin, colistin and polymyxin B, given orally, are often preferred in gastroenteritis derived from *Salmonella* organisms.

When chloramphenicol is given orally, sometimes a loading dose of 2 to 3 gm. precedes the regular administration of 500 mg. every four hours. In patients unable to accept the drug orally, 0.5 to 1 gm. of chloramphenicol sodium succinate is given intramuscularly or intravenously every six to 12 hours.

Sequelae

Aplastic anemia, thrombocytopenia, and granulocytopenia have occurred after both short-term and prolonged chloramphenicol therapy but rarely have complicated its local use, as may happen with use of ocular solutions. Regular studies to detect eosinophilia, leukopenia, anemia, thrombocytopenia, reticulocytopenia, and rising serum iron levels should be carried out. Hematotoxicity may represent an accentuated normal response to the drug, since mild reversible changes are not rare, and large doses given for prolonged periods will cause maturation arrest in a majority of subjects. However, in certain individuals, hypersensitivity probably contributes partially to the drug's hematotoxicity. Hematotoxicity is more frequent in Caucasian girls less than 12 years old. Some recent work indicates that 100 mg. of L-phenylalanine/kg. of body weight per day given orally may ameliorate the hematotoxicity.[2]

Other hematotoxic drugs include the sulfonamides, ristocetin, and less frequently streptomycin and the tetracyclines. Penicillin G, especially when given in large amounts for prolonged periods, rarely has caused anemia, evidently reflecting immune erythrocytic destruction.[3] Novobiocin, griseofulvin, methicillin, oxacillin, colistin, cephalothin, and lincomycin have caused transient leukopenia. Actually, all antibacterial agents have been accused of hematotoxicity on occasion, but contentions against the others are difficult to verify.

The fatal *"gray syndrome"* may occur in infants given chloramphenicol. Anorexia, abdominal distention, lethargy, flaccidity, hypothermia, respiratory distress, and "gray cyanosis" may reflect excessive concentration of the drug because of deficiencies of drug conjugation and excretion due to immature enzyme systems in the infant.

A *"typhoid shock"* syndrome occurs after the drug is used in typhoid fever; the shock, presumably caused by excessive release of endotoxin, resembles so-called bacteremic shock due to other gram-negative bacilli.

Chloramphenicol, streptomycin, and isoniazid are three antimicrobial drugs that may cause optic neuritis. The mechanism of the neuropathy may concern drug-induced pyridoxine deficiency.

Other untoward effects include stomatitis, glossitis, candidal superinfection, rashes, fever, and, on oral use, gastrointestinal irritation.

Polymyxin B

Polymyxin B (Aerosporin) is mainly used against *Pseudomonas* organisms but also is active against *Escherichia coli,* and the *Klebsiella-Aerobacter, Salmonella,* and *Shigella* groups. The drug is essentially lacking in anticoccal effect.

In certain gram-negative bacillary infections such as endocarditis or meningitis, conjoint use of other agents such as a tetracycline or chloramphenicol is considered.

Polymyxin B alone, and together with neomycin, has been administered orally to patients having enteritis from *Salmonella* or *Shigella* organisms; neither drug is well absorbed by the oral route.

A 25 to 50-mg. dose of polymyxin B is given intramuscularly every six to eight hours. Rarely, 50 to 100 mg. is given intravenously once or twice daily. In the azotemic patient, a single intramuscular dose given every two to four days may suffice. The drug is also administered intrathecally, intraocularly, and intrapleurally in doses of 1 mg. Polymyxin B has been given via inhalation, by aerosol directly into a tracheostomy tube, and topically to the ear, nose, and skin.

Untoward effects of polymyxin B include nephrotoxicity, pain on intramuscular injection, fever, flushing, pruritus, superinfection, acroparesthesia, cerebellar ataxia, headache, and a curare-like effect.

Colistin

Colistin differs from polymyxin B in only one of its amino acids and in the configuration of the molecule. Colistin sulfate is used orally while colistin methanesulfonate or colistimethate (Coly-Mycin) is the form used parenterally. The antibacterial spectra of polymyxin B and colistin are identical and there is bacterial cross-resistance to the two drugs. Colistin initially was described as being less toxic than polymyxin B, but more recently this has been disputed.[4] Reportedly, when colistin is used in doses necessary for control of systemic infections, untoward effects occur in 30 to 50% of patients.

Usually 20 to 50 mg. of colistin is given intramuscularly two to three times per day for a maximal daily dose of 150 mg., but some investigators[1] have given 300 to 350 mg/day. There is a special preparation for intravenous or intrathecal use, since the form for intramuscular use contains a local anesthetic.

When amounts of colistin are given to produce an antibacterial effect similar to that obtained with recommended doses of polymyxin B, the untoward effects of the two drugs may be similar. In addition, transient leukopenia, auditory disturbances, and hepatotoxicity may occur after colistin is used.

Cycloserine

Cycloserine (Seromycin) is active against strains of *E. coli* and *Klebsiella-Aerobacter* organisms, but *Pseudomonas* and *Proteus* organisms are often resistant. Tubercle bacilli, *Nocardia* organisms, and some streptococci and staphylococci may also be sensitive to the drug.

In infections due to gram-negative bacilli, cycloserine is used chiefly as a second-line agent in those of the urinary tract.

In normal adults the maximal oral dosage is 250 mg. every six to 12 hours, preferably the latter. To minimize untoward effects, blood concentration should not exceed 25 μg. ml. Untoward effects are likely when more than 1 gm. of cycloserine is given daily, particularly when the individual dose exceeds 250 mg.

Untoward effects of cycloserine include dermatitis, headache, drowsiness, mental confusion, hypomania, dyskinesia, and convulsions. Cycloserine's neurologic effects may be reducible by conjoint administration of pyridoxine. Cycloserine is used cautiously in patients with reduced renal function and is contraindicated in those with epilepsy.

Paromomycin

Paromomycin (Humatin) is used orally in certain cases of enteric salmonellosis, shigellosis, and amebiasis and to suppress the intestinal flora before operation as well as in patients with hepatic coma. To prevent neu-

Continued

rologic complications which may reflect the systemic absorption of ammonia due to the action of intestinal bacteria on dietary protein in patients with hepatic coma, the three drugs most commonly used are neomycin, kanamycin, and paromomycin. All three drugs have in common partial bacterial cross-resistance with streptomycin; that is, a streptomycin-resistant organism may be sensitive to the drugs, but an organism resistant to one of the drugs is also likely to be streptomycin-resistant. In addition, bacterial cross-resistance among neomycin, kanamycin, and paromomycin is usual. Paromomycin is not well absorbed after oral administration and is ineffective in systemic infections.

Paromomycin is given orally in 500-mg. doses four to six times daily; an initial dose of 4 gm. has been recommended. Excessive oral dosage is avoided since the agent is potentially nephrotoxic.

Untoward effects include dermatitis, headache, candidal superinfection, vomiting, and diarrhea. Loose stools after the drug is used may be confused with an underlying disease.

The Mandrake

"And Reuben went in the days of wheat harvest, and found mandrakes in the field, and brought them unto his mother Leah."

From this verse and the three subsequent ones, and substantiated by Bible botany, Genesis 30:14-17 indicates that in Biblical days the mandrake plant was used for a love potion.

Besides being an aphrodisiac it was one of the many highly touted "cures," ancient and medieval. A versatile plant indeed: it was an emetic and purgative, a promoter of fecundity, a narcotic for pain. In fact, if human faith were prodigious enough, a bit of mandrake rhizome could cure anything — from abasia to zoopsia.

Similar to Mandragora and belonging to the deadly nightshade family, mandrakes were superstitiously regarded as partially human plants. Was not *man* their first syllable; did not their bifurcated roots resemble a pair of human legs; and, when forcibly extirpated, did not the plant utter a human shriek that instantly struck dead the man so bold as to disturb it?

For optimum potency mandrakes had to be quickly jerked out of the ground in a graveyard at night in the dark of the moon. Medicinal plants growing anywhere else were only moderately efficacious; but those that sprang up spontaneously in a burial ground were imbued with a special esoteric power acruing to them from the residual life force of the dead on whose graves they flourished.

In parts of Africa the mandrake is still used for its legitimate belladonna properties as a narcotic and antispasmodic.

Publicity is easy to get. Just be so successful you don't need it, and then you'll get it. — Anon

Abstracts, Briefs and Commentaries

INKY-CAP TOXIC REACTION*

An adult woman suddenly became violently ill about one hour after having drunk a glass of sherry in the late afternoon. Her first symptom was the feeling that her head "was swelling." This was quickly followed by "shakiness," "tingling in the toes and fingers," "chills," and "gasping for breath." She also reported flushing and palpitations and stated that although her mind was clear she could not speak. She was able to talk after about one hour, at which time she was put to bed. Symptoms gradually subsided, she slept, and by morning all manifestations of the toxic reaction had disappeared. A physical examination conducted subsequently revealed no abnormalities that could be attributed to the reaction. Her husband, who had also drunk the wine, was not affected.

The important associated history is that the woman is an active amateur mycologist** and had eaten cooked inky-cap mushrooms twice a day for four days preceding the reaction. The husband also had eaten some of these mushrooms during this period, but not so frequently and in lesser quantity.

The inky-cap (Coprinus atramentarius) is a fairly common gill fungus which fruits almost any place where organic debris is present in quantity. It is most frequently seen during the spring and fall in cool wet weather and may be found in gardens, lawns, and around buildings. The popular name is derived from the fact that at maturity the gill structures blacken and liquify.

The mushroom is entirely without untoward effects unless its ingestion is associated with alcohol intake.[1] The effects are due to the presence of disulfiram in cooked C. atramentarius.[2] Other coprinius species apparently do not contain this chemical. Evidence indicates much variability in reaction to C. atramentarius when combined with alcoholic beverages. Buck[3] reports that in some cases the reaction has been observed when the mushroom was eaten during or after alcohol consumption, while in other instances no reaction resulted under these circumstances, but a reaction did occur when alcoholic beverage was consumed 24 hours later.

---

*The State Department of Health would appreciate receiving other reports of this kind of toxic reaction.
**See Test Your Word Score Page 943.

Continued

The onset of symptoms, as in the present case, is abrupt and usually occurs within one to two hours of the alcohol intake. Symptoms are entirely typical of disulfiram-alcohol toxicity, and they are transitory. Factors which affect the severity of the reaction include a variability in the toxicity of the C. atramentarius itself,[1] the time relationship between the ingestion of the mushroom and the alcohol, the quantities of each consumed, and individual sensitivity to the reaction.[4]

Complete recovery may be expected within a few hours, and only conservative symptomatic management is ordinarily indicated. Unusually severe reactions may, however, warrant more aggressive therapy similar to that employed in antabuse-alcohol toxicity.

METASTATIC CARCINOMA OF THE MALE BREAST

Remission by Adrenalectomy

Adrenalectomy has been an accepted and useful method of treatment for metastatic carcinoma of the female breast. Reports concerning treatment for metastatic carcinoma of the male breast have been few. Favorable reports do indicate remission in some cases. The authors report two patients with far advanced metastases who had remissions following adrenalectomies.

Case I. In 1954 a 60-year-old Negro with broken-down primary and large metastatic axillary nodes was treated by x-ray and bilateral orchiectomy. He was not seen again for three years and then reported back with some improvement of the primary lesion; but the arm was edematous. The axillary nodes were positive for carcinoma. Again he was not seen for about two years. There was progressive swelling of the arm, and skin nodules on the chest were numerous. Examination revealed masses in both breasts, increased swelling of his arm, and frozen shoulder and elbow joints. The chest x-ray showed metastases to the lungs with pleural effusion. Bone survey revealed widespread osteolytic and osteobastic lesions. Bilateral adrenalectomy was performed. The glands weighed 23 grams and were partially replaced by metastatic cancer. He was discharged on maintenance doses of hydrocortisone and nine-alpha-fluoro hydrocortisone. Eighteen months later the ulcerative lesions were healed, the arm swelling was decreased, lung metastases were diminished, pleural effusion had not reaccumulated, and skeletal lesions showed reossification. This condition prevailed for nearly another year, after which he underwent a rapid decline.

Case 2. This 50-year-old male had a radical mastectomy for carcinoma together with bilateral orchiectomy. The patient did well for about four years, at which time he developed back pain, pleural effusion and

enlarged supraclavicular glands. The effusion was aspirated and he was put on stilbestrol. Back pain increased markedly. X-ray examination revealed metastases to the skull, the clavicle, the dorsal and lumbar vertebrae, and the sacrum. Approximately five years after his mastectomy a bilateral adrenalectomy was performed. His back pain improved promptly, and reossification of the spine was shown by x-ray. The patient returned to work about one month after his surgery. Reexamination was done, revealing excellent results.
Summary: Case 1. The 60-year-old Negro received great improvement with remission for 21 months. Case 2. The 50-year-old patient with pulmonary and osseous involvement sustained marked remission and continued to work for three years.

The authors report the follow-up on 12 patients who had adrenalectomy with remissions of from six months to five years.

PSYCHIATRIC ILLNESS IN PHYSICIAN'S WIFE

The case records of 50 physicians' wives admitted to a private psychiatric hospital were reviewed to determine what factors were relevant to their illnesses. Most of the patients became ill between the ages of 29 and 35, after the stresses of their husbands' education and early professional adjustment had been overcome. The typical patient first developed her symptoms after 12 years of marriage; the diagnoses, while varying considerably, were characterized by the primary complaint of depression, addiction to alcohol and drugs, or a functional pain syndrome.

Frequently the patient described her spouse as an inadequate father and husband, and more specifically, as undemonstrative, dependent, or domineering. More than one half felt that the frequent absence of the husband was an important factor in their illness, and many of these wives felt that their dependency strivings and sexual wishes were unfulfilled. It seemed, and especially in those suffering from drug addiction, that the patients were often given drugs (generally habit-forming ones) instead of husbandly concern and affection. As a group, these patients appeared somewhat immature and passive, although they had at one time adapted admirably. The author concluded that psychiatric illness and repeated hospitalizations for diverse reasons often indicate a faulty husband-wife relationship in which the wife is progressively excluded from her husband's life and that this neglect and exclusion is a common precipitating factor in the psychiatric illnesses of physicians' wives.

ARTERIAL DAMAGE WITH FRACTURES

Arterial insufficiency and trauma are a bad combination and if not properly attended may lead to crippling disabilities or even the loss of a limb.

Continued

The relatively deep and fixed vessels are the most commonly injured. They may be compressed, acutely angulated, torn, or, in some instances, severed. Cool, pale, dry extremities with hypesthesia, absent pulsation, decreased motor function suggest damage which should be attended as an emergency. There are few contraindications to arteriography which are valuable in identifying any significant arterial occlusion. The cases reported by Bassett and Silver indicate complete obstruction of the femoral artery from a fracture at the sacroiliac joint with compressive occlusion; a fracture about the knee from compound injury of the tibial head, and thrombosis of an internal carotid artery resulting from extensive contusions about the chin and neck.

Treatment consists of stellate ganglion block in arterial occlusion about the elbow resulting from spasm. When an artery is damaged it should be repaired by simple suture, autogenous graft, or prosthetic graft, in that order, depending upon the circumstances.

In most instances fracture fixation should be accomplished prior to arterial repair. The purpose of arterial repair is to restore the normal circulation in peripheral tissues in an effort to salvage as much of the extremity as possible.

POSTSPLENECTOMY THROMBOCYTOSIS

Postsplenectomy thrombocytosis is a complication of splenectomy about which little information has been published. Two out of 3 patients suffering with this disorder and seen in the past 2 years had thromboembolic complications apparently related to their thrombocytosis; the third had hemorrhagic manifestations. Coagulation studies performed on the patients with thromboembolic difficulties revealed no abnormalities except for platelet counts which had risen from normal preoperative levels to as high as 1.37×10^6 postoperatively. Both patients had multiple pulmonary infarctions. Both symptoms and platelet levels were well controlled with small doses of uracil mustard. The patient with hemorrhagic manifestations showed abnormalities in thromboplastin generation partially corrected by normal serum, alumina absorbed plasma, and dilution of the patient's platelets. At this time, the platelet count was 2.64×10^6/cu. mm. Following therapy with uracil mustard, the platelet count fell to normal levels, the thromboplastin generation test reverted to normal, and the patient became asymptomatic. In any patient who has ever undergone splenectomy, the occurrence of hemorrhagic or thromboembolic manifestations should cause one to consider the existence of postsplenectomy thrombocytosis.

Derivatively Speaking

Artery — from Greek *aer* (air) + *terein* (to keep), because the ancient Greeks thought the arteries held air.

Book Reviews

Books must follow sciences, and not sciences books. — Bacon

SYMPOSIUM ON CATARACTS — **Transactions of the New Orleans Academy of Ophthalmology, St. Louis. C. V. Mosby Co., 1965. 340 pages, illustrated, chapter references, index, price $19.50.**

The material found in this book consists of the lectures and "round table" discussion of guest speakers at the New Orleans Academy of Ophthalmology Midwinter Symposium on cataracts held in New Orleans, February 16-21, 1964.

With the exception of the first chapter on the differential diagnosis of leukocoria (white pupil) in children, the special material would make interesting reading only to an ophthalmologist. The presentations are thought provoking, well illustrated, and contain numerous references. There is more than the usual number of proof-reading errors which contribute to the reader's harassment, but all in all the editors are to be congratulated for making the material available to those of us unfortunate enough not to have been in New Orleans during February 1964.

William S. McClanahan, M.D.
Minneapolis, Minnesota

FOUNDATIONS OF ANESTHESIOLOGY — **Albert Faulconer and Thomas E. Keys. Cloth. Pp. 1337. Charles C. Thomas Co., Springfield, Illinois. 1965.**

These two volumes represent a significant contribution to anesthesia literature. The compilers have assembled a representative group of "classic" writings to tell the story of the development of modern thought and practice in anesthesiology. Translation from another language was necessary to make many of the early works in this field available to the English-speaking world.

The compilers divide the study of anesthesia principles into eight subjects, including respiratory physiology, theories of narcosis and inhalation, rectal, conduction and intravenous anesthesia. The format of this book has been designed to present reports of significant ideas in their original form as they pertain to the progress of knowledge in a given field. For each of the selected subjects, these works are given in the chronological order of their appearance in the literature.

No attempt has been made to abstract, condense or interpret any of these writings. Some of the material presented has been proven to be erroneous but is included for obvious reasons of historical interest.

The appeal of such a book, as a personal possession, is limited primarily to students and instructors of anesthesiology, to research workers and to those persons who have a particular interest in the development of scientific ideas through several generations. These volumes should certainly be included in medical libraries. They fill a reference material void that has never been seriously approached heretofore.

CORRECTABLE RENAL HYPERTENSION — **Chester C. Winter, M.D., F.A.C.S. Lea & Febiger, Philadelphia, 1964.**

The complexities and vagaries of hypertension caused by renal disfunction are brought into sharp focus and fine perspective by a contemporary pioneer in renal disease. The author has contributed greatly to our clinical management of hypertensive patients with introduction of radioisotope renography and methods of performing divided renal function tests. His concise and readable textbook provides basic information in all major aspects of kidney disease as it relates to hypertension. Various conflicting theories of the etiology of renal hypertension are objectively and effectively discussed and the chapters on physiology are excellently written. The author presents currently accepted techniques for correction of reduced blood flow to the kidney and summarizes results obtained by various authors. This book is of particular value for medical students, interns, and residents as they seek to familiarize themselves more completely regarding this fascinating and newly burgeoning field of medicine.

PRODUCT NEWS

Pentyex-MPL

As we study the geriatric patient, we find many of them require a cerebral stimulant for sustained treatment. Some of these patients are mildly confused, have memory defects and apathy. The action of the ingredients supplied in Pentylex Elixir has proved 100 per cent effective in over two-thirds of the patients treated on a continuing basis with pentylenetetrazol alone. Pentylex Elixir supplies (in a fine wine base) not only pentylenetetrazol but also thiamine, niacinamide and cyanocobalamin, other essentials often required by these patients.

Minnesota Pharmaceutical's Pentylex is also available in an injectable form which includes the liptotropic factors of choline, methionine, and inositol as well as B-12 and other B-complex factors.

First National Congress on Medical Ethics

Sponsored by Judicial Council
American Medical Association
March 5-6, 1966 — Chicago

The first National Congress on Medical Ethics was keynoted by James H. Berge, M.D., of Seattle, Washington. He pointed out that the purpose was to retain valuable ethics which have evolved from experiences in the past, to provide for the needs of the present, and to plan for possible changes in the future.

In most medical schools there is no course of instruction dealing with ethical considerations; but each graduating student receives from the American Medical Association a booklet outlining the principles of medical ethics to which he is expected to adhere.

Professional Ethics in a Time of Change — Everett Hughes, PhD.

Though the high principles of medical ethics can be emblazoned in the sky, the working rules which make them effective must be flexible enough to change with changing times.

Dr. Everett Hughes of Brandeis University, Waltham, Massachusetts, pointed out that the ethical errors of one individual reflect on the entire profession and, therefore, it is not the responsibility of the society to protect the errant member. The public do not doubt the judgments of their own physicians and often have more faith in them than their fellow physicians have.

Medicine — A Profession or a Business — James Z. Appel, M.D.

Dr. Appel, 120th President of the American Medical Association, speaking on Medicine as a Profession or a Business, reminds us that the inability to practice medicine may be physical, mental or professional, and that only a small percentage of physicians fall into the category of being dangerous.

Disciplinary problems that are encountered originate from the incompetent physician. Dr. Appel concurs in the recommendation of Dr. Derbyshire who has stated that, as much as possible, misconduct should be handled at the lowest level, starting with the staff. Recalcitrant members should be referred to the Grievance Committee or to the local and state society only if the problem remains unsolved. He further points out that in order to provide good public service a physician must practice self-denial, self-evaluation and self-discipline. In order to prove the true spirit of his professionalism he must render proof of his competence by being humanitarian, showing professional independence, and accepting no dictates from those not qualified to give them. He must resist interference, minimize business and financial reward, and maximize service to humanity.

Economics or Ethics — Russell B. Roth, M.D.

Dr. Roth, Chairman of the Council on Medical Service dealing with ethics and economics, pointed out that the economically and ethically sound physician causes no concern and is successful; the medically unethical physician may have difficulty within his profession; whereas the unethical

Continued

but economically-sound physician falls into the category of charleton or quack.

The physician should seek remuneration only for services performed, and his fees should be commensurate with the services rendered. Dr. Roth pointed out that the medical credit card which is being sponsored in some areas would be considered ethically out of bounds at the moment because there might be a tendency to overcommercialization. He reminded us that any form of fee-splitting is truly not in the interests of the patient.

Medical Ethics — **Robert Mayo Tenery, M.D.**

Dr. Tenery from Waxahachie, Texas, dealt with the etiquette of referrals and has suggested some rules for both the referring physician and the consultant.

Suggestions for the Referring Physician

1. Select ethical consultants of dependable ability who are courteous to your patients, charge reasonable fees, and will take your charity patients as well as your paying patients.

2. Know your consultants personally.

3. Make appointments for consultations yourself and talk with the physicians when possible.

4. Send the consultant a written summary which includes your history of the case, physical and laboratory findings, treatment and opinion of the case. Also give an indication of what you have told the patient and family, a description of any special personality traits in the patient, and a definite statement as to whether you wish merely an opinion or both opinion and treatment. Furthermore, you should tell the consultant if the patient's financial limitations may require a reduction in his usual fee.

5. Do not limit the consultant by telling the patient that a specific operation or treatment will be done; instead, tell the patient that he is being referred for an operation or treatment if the consultant agrees that it is indicated.

6. In surgical patients do not force the consultant to accept you as his first assistant. A surgeon often can do a better job when assisted by one who is familiar with his technique.

7. Give the patient an appointment for a follow-up visit. At that time you can evaluate his opinion of the consultant.

Suggestions for Consultants

1. Follow the request of the referring physician and do not take over the treatment without his permission.

2. If possible, call the referring physician immediately after you have seen the patient.

3. When another ailment is discovered, talk with the referring physician before treating this condition or referring the patient to another specialist.

4. Send a written report to the referring physician as soon as possible. This should include your findings, opinion, treatment (if any), recommendations and disposition of the case.

5. Never degrade the referring physician and be cautious in commenting on anything that he has said or done.

6. In arriving at your fee, take into consideration the patient's ability to pay the referring physician's fee plus your own.

7. Be certain that the patient returns to the referring physician when you have completed the requested service.

From the Workshop

The afternoon sessions were divided into small discussion groups in which doctors were able to express their opinions informally.

Grievance Committee — **Henry Crawford, M.D.**

From the Grievance Committee group, the consensus of opinion was that this committee should be composed of doctors only, and that it should be so handled as to provide proper public relations between disputing doctors. Most of the grievances, it was pointed out, can be handled informally and many of them by telephone. It was suggested, however, that those members who are on the Grievance Committee should check with their malpractice and liability insurance to determine whether or not they are covered against liability for slander arising out of the dissatisfaction of one who is being disciplined.

Discipline Committee — **William J. Kelly, M.D.**

From the Discipline Committee it was concluded that soft discipline by the lowest level of the local society should first be undertaken. Anyone who is being disciplined should be advised of his rights to appeal to a higher authority if he so desires. It was the consensus of the group that our obligation is to govern ourselves, but that the code of medical ethics must be satisfactorily adhered to. It was further suggested that the public be informed that we do discipline our own members.

Interpretation of Unethical Conduct by Local Standards

— John Burkhart, M.D.

Interpretation of unethical conduct on the part of an individual should be based on local standards, and it was the consensus of this committee that the problem of fee-splitting should be handled in accordance with the ethical principles set out by the American Medical Association: that a charge be commensurate with the services rendered and an assistant's fee be paid by the patient to the assistant, and that the referring physician use an assistant only if it is indicated. Overtreatment of a patient was frowned upon as being too commercial and thereby a violation of the code of ethics.

Medicine and Pharmacy Committee — Marvin Johnson, M.D., Moderator

Owning a pharmacy within the reach of one's own prescriptions would not constitute good ethics, and prescribing medications under a code name without the privilege of receiving full descriptions of the ingredients would likewise be considered poor ethics.

AMA
115TH ANNUAL CONVENTION • McCORMICK PLACE • CHICAGO • JUNE 26 - 30, 1966

CXV 1966

Chicago, the convention capital of the world, hosts the world's largest medical convention. Each year the AMA Annual Convention presents a wider and greater range of medical subjects. This year's convention will be held in magnificent McCormick Place. Air-conditioned, it offers almost unparalleled facilities. View and participate in the following: • Six general scientific meetings • 23 medical specialty programs • 800 scientific and industrial exhibits • Lectures, panel discussions, motion pictures and color television. Plan to attend—continue your post-graduate education.

See JAMA May 9 for complete scientific program—forms for advance registration and hotel accommodations.

Tumor Registries in Minnesota

J. JEFFREY MCCULLOUGH, M.D.*
WILLIAM C. HARRISON, M.D., M.P.H.**
DEAN S. FLEMING, M.D., M.P.H.†
Minneapolis, Minnesota

THE STATISTICAL analysis of data pertaining to large groups of cancer patients is a valuable tool in cancer investigation. It has led to the development of many types of tumor registries where basic information and follow-up reports on each patient can be accumulated.[1-3] In 1950 there were 4,375 resident cancer deaths; 90 per cent of Minnesota hospitals reported a total of 8,445 cancer cases.[4]

There are different types of registries, each with a different goal. As described by Ringel,[5] the three basic types of tumor registries are: the very limited registry which is concerned with only one particular type of tumor (breast, thyroid, lymphoma, etc.); the epidemiological registry which involves detailed analysis of each case with attempts to make correlations of etiological significance; and the most widespread type of registry which is that found in many medium-sized hospitals. The latter type uses a limited amount of data about each case, performs some statistical studies, and serves as a basis

for "assessing the quality of care received by the patient and the effectiveness of diagnostic and therapeutic measures."[6]

Tumor Registry Hospitals

There are at present 186 hospitals[7] with 16,471 beds in Minnesota which care for acutely-ill medical and surgical patients. The 17 hospital tumor registries represent 3,731 beds or more than one fifth of the medical and surgical hospital beds for the acutely-ill in the state.* (See Table 1.)

During 1963, 126,071 patients were admitted to the 17 hospitals which comprise the basis of this report, representing an average of 7,416 annual admissions per hospital. Approximately 2.1 per cent (2,663) of these patients were entered into the tumor registries. The duration of the average hospital stay was 7.8 days with a range of 5.9 to 14.3 days.

Present Status

Survival

From 1957 through 1963, a total of 16,834 patients had been entered into the Minnesota tumor registries (Table 2). A follow-up survey was made during early 1964, which

showed that 49.0 per cent of all patients were surviving at that time (36.6 per cent surviving free of cancer, 9.7 per cent surviving with cancer, and 2.7 per cent surviving with unknown status in regard to cancer).

Absence of Neoplasia

At last follow-up, more than one third of the patients (36.6%) were living free of cancer, an additional 5.9 per cent having died of causes other than cancer.

Multiple Tumors

There was a 1.4 per cent incidence of multiple primary malignancies.

Distribution by Site

The distribution of the tumor registry cases by site in the participating hospitals is shown in Table 3. In general it appears that larger hospitals register more cancer cases, have a longer patient stay and a higher ratio of cancer cases to bed capacity, and tend to have more tumors of the oral cavity and of the respiratory, male genital, urinary, lymphatic and hematopoietic, and central nervous systems. Smaller hospitals with a shorter patient stay and a lower ratio of cancer cases to hospital beds have a higher proportion of tumors of the breast, female genital system, and skin.

In Minnesota malignancies of the breast, female genital tract, oral cavity, and skin account for a larger portion of the cancer registry cases than would be expected on the basis of deaths from these neoplasms in the state (Table 4 and Figure 1). Improved methods of diagnosis and treatment have lowered the proportion of deaths caused by some of these neoplasms and at the same time increased the number of these cases treated in hospitals which have cancer registries.

TABLE 4

Cancer Registry Cases by Site From 1957 Through 1963 Compared with Cancer Deaths in Minnesota During 1963

Continued

Functions of a Hospital Tumor Registry

A hospital tumor registry is intended to serve the hospital staff and patients as a means for improving services to cancer patients within that hospital, not merely as a repository of unused information. Ideally the tumor registry serves as the focal point of the hospital's cancer activities. It makes available to each hospital information about its own cases, not abstract survival rates compiled by a distant medical center which specializes in the care of cancer patients. At regularly scheduled tumor conferences this data should serve as a background for the discussion of the etiology, diagnosis, and treatment of malignant diseases. Several hospitals have very active tumor boards. Some have luncheon meetings at which time all new cases are presented, and pathology slides and x-rays are shown. One tumor board reviews nearly 400 cases a year; its average attendance is 30 physicians.

TABLE 6
Percentage Distribution by Site of 2,150 Malignant Neoplasms at Hennepin County General Hospital Compared with Other Minnesota Tumor Registries

	Hennepin County General	Other Minnesota Registries	All Registries Including Hennepin County
Oral Cavity	8.1	3.2	3.8
Digestive Organs	23.7	24.8	24.7
Respiratory System	6.9	8.4	8.3
Breast	8.7	13.5	13.0
Female Genital	11.6	15.1	14.7
Male Genital	8.9	7.6	7.7
Urinary Organs	5.3	5.8	5.7
Lymphatic and Hematopoietic	5.4	7.3	7.1
Skin	12.2	7.4	9.1
Central Nervous System	2.3	1.4	1.5
Other	6.9	5.5	4.4
Total Number	2,150	17,301	19,451

The tumor registry also serves to remind physicians when periodic follow-up examinations are due for particular patients. The data in these registries is more than adequate for an annual report which may include the distribution of cases by site, the per cent of diagnoses histologically proven, the trends in mortality in an individual hospital, and the completeness of follow-up care patients receive.

At some hospitals the tumor registry serves additional functions. For instance, in county institutions where large numbers of patients are attended by a continually changing house staff, problems of follow-up often arise, and patients may not receive periodic examinations for the early detection of recurrences. A tumor registry can serve as the agency for continuing contact with the cancer patients and can assist the staff in providing good follow-up care. An example of this system is presently operating in St. Paul. Many cases temporarily lost, then relocated by the cancer registry, are found to have early recurrences that would not have been diagnosed until the patient became symptomatic and sought medical attention.

TABLE 5
Present Status of 2,062 Patients in Hennepin County General Hospital Tumor Registry Compared with 16,834 Patients Entered into Remaining Minnesota Tumor Registries

	Hennepin County General		Other Minnesota Registries		All Registries Including Hennepin County	
Total living	29.0%		49.0%		45.9%

Lost to follow-up	16.7%		2.4%		3.9%	
Total number of cases	2,062		16,834		18,896	

Summary

During the past 35 years there has been a gradual development of the tumor registry system in the United States to its present form involving registries with different emphases and goals. This report concerns 17 hospital registries which have been co-ordinated by the American Cancer Society and the Department of Health since 1957. More than one fifth of the acute hospital beds in the state are represented. From 1957 through 1963, 16,834 patients with 17,080 tumors were entered into the registries for an average of 2,405 patients each year. Almost one half of these are now surviving; and well over one third were free of malignant disease at last follow-up. Only 2.4 per cent were lost to follow-up during the seven-year period of this report. The digestive system was the most common site involved, accounting for almost 25 per cent of the tumors. The distribution of cases by site is presented, and a brief discussion of the functions of a cancer registry is given. Some of these registries serve the patient directly, some more indirectly. They all attempt to stimulate interest in cancer activities in the individual hospital, encourage physicians to continue patient follow-up, and thus ultimately benefit the patient.

Tumor Registries in Minnesota
Addendum

Since this article was submitted for publication, data have been received from the tumor registry at Hennepin County General Hospital, Minneapolis. Table 5 shows the condition of 2,062 cancer patients at General Hospital at the time of last follow-up and compares these figures to the averages for the other seventeen registries. The per cent of Hennepin County General patients who have died (54%) is greater than the average. However, this figure approximates that obtained from other hospitals in this group which care for large numbers of cancer patients. The largest proportion of patients who were dead at last follow-up was 63 per cent. It should be re-emphasized that these figures include patients with varying lengths of survival and thus are not comparable to standard survival rates.

The distribution by site (Table 6) for Hennepin County General Hospital is not strikingly different from the average site distribution for the other seventeen registries. There is a somewhat higher incidence of oral cancer and lower incidence of breast and female genital tumors at Hennepin County General. A similar distribution was found at Ancker Hospital.

A Privileged Class

Most humans have doubt at sundown on many a day as to whether anything has been accomplished by them to advance the cause of mankind, or make this a better world. You've sold some groceries, written some editorials, sawed some wood, cooked some meals, written a few pages of a book or milked some cows.

Maybe you've done your best. But it's a long way from the hopper to the grist, and when the shades of evening fall the average tired soul will inescapably turn on himself with "So what?"

But a doctor who has gone into lonely and discouraged homes, where there was fear for the sick, and no one else at hand to administer remedy and give hope, can really say, "I amount to something. I'm worth while."

— Carlton K. Matson (1890-1948)

Photographic Contest

The Editors of MINNESOTA MEDICINE, in collaboration with the Doctors' Photographic Society of Minneapolis, take pleasure in announcing a monthly photographic contest. The contest is to promote an interest in photography in the medical profession. First prize each month will be publication in full color of the winning picture in MINNESOTA MEDICINE.

The following rules will govern the conduct of the contest:

1. Only doctors of medicine are eligible to submit pictures, and the picture must have been taken or composed by a physician.
2. Each contestant may submit not more than two pictures each month.
3. Only color transparencies, 35 mm. to 2¼", can be considered.
4. Each slide should be labeled with the maker's name, address, and the identifying title.
5. Slides should not be mounted on glass, but can be protected in plastic sleeves or envelopes.
6. Each entry must be accompanied by a self-addressed, stamped envelope if return of the picture is desired. Returns will be made shortly after the close of the contest each month. The winning photograph will be retained but will be returned after it has been used.
7. The deadline date for entry will be the 10th of each month and the winner of each month's contest will be announced in MINNESOTA MEDICINE in the subsequent issue. The date of publication will be three to six months in advance.
8. There will be no limitation on subject material except as indicated in item 10.
9. Model releases will be requested of winners where appropriate.
10. Judges will be selected by the editors of MINNESOTA MEDICINE and the Doctors' Photographic Society. The judges will be guided by the precepts of the Photographic Society of America, and winners will be based on appropriateness, interest, impact, and technical excellence.
11. The editors of MINNESOTA MEDICINE and the Doctors' Photographic Society cannot be responsible for entries lost or damaged, but every effort will be made to protect submitted pictures.

Your pictures are hereby invited. Please submit pictures to:

History of Medicine

The Rare Book of the Minnesota Bio-Medical Library

— a browser's view —

MARVIN SUKOV, M.D.*
Minneapolis, Minnesota

Although no one is likely to accuse Sir William Osler of idle boasting over his bibliophilic conquests, it now appears incredible that he and Dr. Harvey Cushing had shown in one exhibition six copies of the first edition of Vesalius. And while this in itself is a sufficiently enviable achievement, the great physician goes on to relate that during his lifetime he distributed copies of the Fabrica to six libraries, including the Boston Library Association and the McGill University Library. Then one day, forgetting his earlier benevolence, he offered copies of this rare book to these same libraries, only to be confronted with the invaluable gift he had previously made.

The fact that during the last generation original editions of works by medical innovators have increased in scarcity and monetary value can make us all the more grateful for the vision and zeal of Dr. Owen W. Wangensteen who made possible the Rare Book and Medical History Unit as part of the Bio-Medical Library in Diehl Hall. The story of the acquisition of funds, the search for rare volumes, the planning of the physical facilities must one day be told by himself; but rumor has it that Dr. Wangensteen was not above absenting himself from a medical meeting to pursue some elusive quarto.

While the principal interest of this collection is in the historical development of medical concepts and practice, the three thousand volumes afford the student and bibliophile a view of the development of the printing art, bookmaking, and illustration, from the mid-fifteenth century to the 1850s. It is a viable, working library with an inclusive chronological and geographic distribution. Original sources are the rule, but when otherwise not available, many items are represented by facsimiles.The Egyptologist and medical historian of preclassical cultures would seek out the original Edwin Smith Papyrus at the New York Academy of Medicine and go to Leipzig for the Papyrus Ebers. The student in Minnesota can pore over accurate reproductions of these rarities and even find a facsimile of the 1412 manuscript of John Arderne's *De Arte Phisicali et de Cirurgia,* along with others of similar nature. From the standpoint of bookmaking, the volumes range from the heavy oversize tomes of Hippocrates, Vesalius, Cowper and the Paolo Mascagni (1752-1815) anatomy with its full scale anatomical illustrations, to numerous Galenic miniatures that must have been pocketed with the devotion given a religious missal. There are ample examples of printing on parchment and fine rag paper; bindings vary from contemporary leather with brass clasps to parchment and linen; illustrations and title pages range from the elementary essential components to massively florid baroque woodblocks.

In its architectural plan this Rare Book Department is designed to serve the needs of research, teaching, and study. It has a lecture hall, class room, administrative offices, spacious exhibit hall and display cases: all with cheerful color schemes — definitely out of the fumed oak tradition — and with good lighting and air control. The book stacks, classified on the basis of life sciences under Botany, Zoology, Medicine, Dentistry, Nursing, Public Health, and Pharmacology, are housed in a well-lighted room under constant humidity and temperature. A catalogue, now in preparation, will enable the reader to select his title and have it delivered to him at the desk or to one of forty-five study carrels. Open-shelf selection, a feature of the other

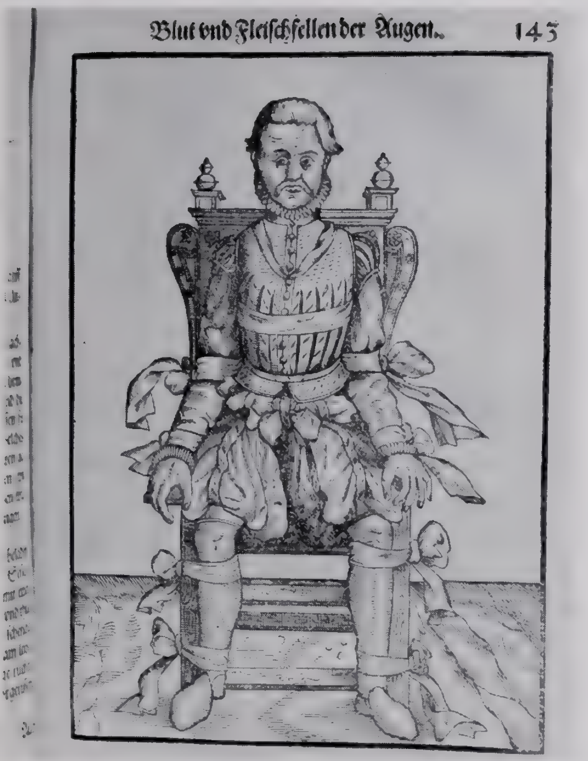
units in the Bio-Medical Library, is not a feasible accommodation for rare books.

One of the prize items in the library is a fifteenth-century manuscript of forty-five leaves with two colored drawings. It contains a brief text on the complexions and humors, a good diagram on urinoscopy, and an illustration based on the anatomy of some animal. The "imaginary" anatomico-physiological illustration antedates the anatomist from Brussels by a little over a century (Figure 1).

Among several incunabula is the first edition of a popular work entitled *Versehung von Leib, Seele, Ehre, und Gut* (Care of the Body, Soul, Honor, and Wealth), printed by Wagner in Nuremburg, 1489, and containing inclusive instructions all the way from nursing the sick to making a will. It is a fine copy, in its original leather with brass corners and locking hinge, printed in German Gothic with block floral initials. The flyleaf, an illustrated water color, shows a pallid patient in bed, and standing by him are a nurse, a physician, and a priest, with a professional mourner seated at the foot of the bed, awaiting the outcome. Another incunabulum is a thin 80-page volume of Mondino de Luzzi, who taught at the University of Bologna and published a manual of human dissection in 1316. Although Mondino dissected an executed criminal and is credited with reintroducing human dissection, he followed the continental Galenic description of the various organs and, curiously, the only woodcut in this volume shows a "professor" on a high-backed chair directing his "student" in the dissection. Anatomical illustration had not yet made its entry.

Hans von Gersdorff (fl. 1490-1520) practiced as a military surgeon for forty years, and while he opposed Pare's innovations, he was generally more conservative than his predecessors in wound treatment and inclined to the use of warm, not boiling, oil, as a dressing, as well as to the covering of an



Blut vnd Fleiſchfellen der Augen. 143

Fig. 3 — Georg Bartisch, *Ophthalmodouleia*, 1583.

amputation stump with a flap of skin and muscle. He is here represented by the rare second edition of *Feldtbuch der Wundartzney* (Strassburg, 1526), parchment bound. The volume has several woodcuts depicting such things as an instrument for removing depressed skull fractures, the application of variously shaped cauteries, instruments for reducing fractures of the extremities (Figure 2) and the first known illustration of an amputation. A companion volume to von Gersdorff is Hieronymus Brunschwig's *The Noble Experyence of the Vertuous Handywarke of Surgeri*, London, 1525. First published in 1497, it has priority as the first detailed account of the treatment of gunshot wounds. Peter Uffenbach's (d. 1635) huge, single-volume, surgical anthology of 1164 pages plus a detailed index, published in Franckfort in 1610, is also available, printed in small Roman type and parchment bound. The greying rag paper is still vital and pliable. Another noteworthy volume is the *Thesaurus Chirurgiae*, copiously illustrated with black and white woodcuts and closing with a flamboyant colophon — a richly-ornamented square woodcut of a wreathed male figure riding a winged stag and wielding a serpent in his left hand and a serrated sickle in his right.

The Vesalius is a fine second edition copy (1555) and is essentially identical with the first edition, except that a few changes have been introduced in the cardiovascular system. All the drawings were made by John Stephen of Calcar, a pupil of Titian, and were transported across the Alps to Basel for the press of Johannes Oporinus (1507-1568), the printer of Luther's writings. The fine lettering and good presswork, along with the superb illustrations, have made this a typographical as well as a medical classic.

Within a year of the publication of the Fabrica, Johannes Froben (1460-1527), printer for Erasmus and publisher of several works of the church fathers, issued the first Greek Galen. The volume in the Minnesota collection has over 1500 double-column pages in heavy Roman type. It may be noted that England, in spite of the efforts of Linacre and others, was slow to turn from Latin to the original Greek for the writings of Galen. Nonetheless, from the beginning of printing to the end of the sixteenth century, or during a period of about one hundred and fifty years, over a hundred publishers were putting out Galen's works in France, a somewhat larger number in Italy, and seven in England. There are some forty copies of Galen in the Minnesota collection, attesting to his popularity, which continued into the nineteenth century.

The worm-eaten condition of the extremely rare first edition of *Ophthalmodouleia* of Georg Bartisch (1536-1607) adds to its interest. Bartisch gives preoperative procedures for both the patient and the operator: the former to abstain from food and the latter from drink and venery. Considered the founder of modern ophthalmology, his book is well illustrated with superimposed anatomical plates and is presumed to contain the first detailed procedure on excision of the eye in man (Figure 3).

The seventeenth century has fulsome representation from Thomas Willis (1621-1675) and Thomas Sydenham (1624-1689).

Continued

Latin was still the rule until the end of the seventeenth century, and both of these English pioneers have their work available in the original as well as in translation. Sir Christopher Wren illustrated Willis' *Cerebri Anatome* of 1664 (found in the Minnesota collection in a later edition of his *Opera Omnia*).

Going into the eighteenth century one encounters Herman Boerhaave (1668-1738) on diseases of the eye, Nicholas Andry de Bois-Regard on orthopedics in an English edition of 1743, and an early volume of Thomas Bartholin (1616-1680), the last a presentation copy to Dr. Wangensteen on the occasion of his Samuel C. Harvey lecture at Yale. As one gets further into the eighteenth and early nineteenth centuries, the library holdings grow too numerous to list even the more important items.

Gulliver's Travels — Jonathan Swift*

Gulliver, who had been employed as a surgeon on the sailing vessel, Adventure, encountered illness among his sailors and because of their dissatisfaction with his services they cast him onto an island ruled by a herd of Victorian horses. He learned to speak their language and found them to be a very noble species which knew no evil and lived by the infallible laws of nature. A species of monkey-men called Yahoos, having the physical characteristics of humans and, in addition, possessing all of the evil characteristics inherent in man, were held in subjugation by the noble horses.

In one of their conversations the master horse desired to know from Gulliver the reason for such unaccountable evils as he had catalogued in describing the people of his homeland.

Gulliver — On the Dissipations of Humans

"I told him we fed on a thousand things which operated contrary to each other; that we ate when we were not hungry, and drank without the provocation of thirst: that we sat whole nights drinking strong liquor without eating a bite: which disposed us to sloth, inflamed our bodies, and precipitated on prevented digestion. That prostitute female Yahoos acquired a certain malady, which bred rottenness in the bones of those who fell into their embraces: that this and many other diseases were propagated from father to son; so that great numbers came into the world with complicated maladies upon them.

That besides real diseases, we are subject to many that are only imaginary, for which the physicians have invented imaginary cures; these have their several names, and so have the drugs that are proper for them; and with these our female Yahoos are always infested."

Medicine and Religion

The Difference Between Psychiatry and Religion*

IN HELPING people in distress, there is no argument that psychiatry and religion should not cooperate; but the two fields are different. The professionals involved have different roles, use different languages and symbols, and are under different auspices with different functions. Boundaries should be defined, so that each can understand and evaluate the efforts of the other.

The main function of psychiatry is diagnosing and then making a disposition. The basic function of religion is worshipping God and advocating a moral life — not relieving anxiety or solving problems. In order for a psychiatrist to function and utilize psychotherapy, he must have a diagnosis. Clergymen on the other hand, do not need a diagnosis; all that is essential is the call or need for help.

Psychotherapy is an integral part of the practice of medicine and is a controlled scientific technique with different therapies for different categories of mental illness; to be practiced effectively psychotherapy requires a broad background of medical knowledge, special skills, and much experience after training. This does not mean, however, that the clergy do not have at their disposal other methods more comparable to first aid and including management, advice giving, teaching, and counselling. In fact, clergymen are important front-line mental-health workers, since the largest percentage of patients with emotional illness consult their clergymen first — actually 42%. Twenty-nine per cent consult their family doctors; 18% consult psychiatrists and psychologists, and 10% consult social agencies or marriage clinics. In this same study,[1] follow-up of those seen first by the clergy reveals that one of three was eventually found to be severely ill psychiatrically, and yet only one of ten had been referred by the clergy for psychiatric help. This indicates that clergymen need more training in order to proceed more effectively in the mental-health field.

Since clergymen are in the so-called "front line" and people who are "hurting" consult them first, it is important that psychiatrists, as well as physicians in general, should recognize the distinct qualifications of the clergy in special areas. Clergymen are most valuable when a religious person is suffering the severe consequences of real guilt; it is then that psychiatrists should refer that stricken person for forgiveness and guidance and should not institute psychotherapy. On the other hand, if distress results from guilt that has no basis in reality, the patient should be in the hands of a psychiatrist and so referred by the clergy. The clergy should limit themselves to reality problems.

In dealing with "front line" emotional emergencies and in counselling, the clergyman has some unique aspects which psychiatrists do not have.

1. He is considered a friend by the disturbed person and family and can even come in to help without being called directly.

2. He is around at times of stress, which include weddings, funerals, baptisms, etc.

---

*Presented at the Symposium on Medicine and Religion presented at the meeting of the Hennepin County Medical Society on March 7, 1966.

Continued

3. He can give advice, castigate, rebuke, inspire, encourage, console at appropriate times. This function can and should include helping his congregation to accept psychiatry as an integral branch of medicine.

4. He stands in place of God, can use prayer, give absolution, and help to save souls.

5. He can give money, food, shelter.

In the above capacity, each clergyman is committed to his moral and religious code and preaches it publicly to his congregation; while the psychiatrist's ethical and religious beliefs are private, and he is not the custodian of his patient's morals as is the clergyman. The psychiatrist has only one role to play for each particular patient, namely, that of psychotherapist and physician, while the clergyman has many roles to play.

The Minnesota State Board of Medical Examiners

Notice is hereby given, pursuant to the provisions of Minnesota Statutes, 1965, Section 15.0412, that the Minnesota State Board of Medical Examiners will hold a public hearing on Saturday, July 16, 1966, at 10:00 o'clock a.m. in the Colonial Room of the Lowry Hotel, Saint Paul, Minnesota, on the adoption of the following proposed changes in the Rules and Regulations of the Minnesota State Board of Medical Examiners:

1. The adoption of a new Rule and Regulation ME 7 (a) (8) reading as follows:

"(8) On all applications filed on or after July 1, 1968, evidence satisfactory to the Board that the applicant has been awarded a Standard Certificate by the Educational Council for Foreign Medical Graduates, certifying to the applicant's formal education, his having passed the ECFMG English test, and his having passed the American Medical Qualification Examination of the ECFMG."

The effect is that from and after July 1, 1968, graduates of foreign medical schools who apply for admission to a licensing examination must furnish evidence satisfactory to Minnesota State Board of Medical Examiners that the applicant has been awarded a Standard Certificate of The Educational Council for Foreign Medical Graduates, in addition to the other information required by ME 7 (a).

2. The amendment of Rule and Regulation ME 6 by striking and deleting therefrom ME 6 (b) (6) and by substituting in lieu and in place thereof:

"(6) Evidence satisfactory to the Board that the applicant has been awarded a Standard Certificate by The Educational Council for Foreign Medical Graduates, certifying to the applicant's formal education, his having passed the ECFMG English Test, and his having passed the American Medical Qualification Examination of the ECFMG."

The effect is to conform to present practice by eliminating the requirement by applicants for a temporary certificate for graduate training, that they be registered by Minnesota State Board of Examiners in the Basic Sciences, and by substituting the requirement that they have been awarded a Standard Certificate of The Educational Council for Foreign Medical Graduates, in addition to the other information required by ME 6 (b).

J. P. Medelman, M.D.
Secretary-Treasurer

HEARING · SEEING · LEARNING

Special Report

Pre-School Survey Saves Vision and Hearing

A PUBLIC HEALTH nurse advises that a child who has long been a behavior problem be given an eye examination because his eyes appear to be slightly crossed. Correction of the eye defect results in improved behavior. A child in a school for the mentally retarded is found to have a severe hearing loss. Further testing indicates that his IQ has been grossly underrated.

A child's loss of sight or hearing are subtle defects. Too often they go unnoticed because there are no manifest symptoms, or the parents of the child may not be knowledgeable about eye and ear health and do not recognize the danger signals. The only effective way of detecting these children on more than a piecemeal basis is through screening.

Obviously, the medical profession is not numerically strong enough to conduct the kind of screening which would be necessary to detect the children who are victims of eye and ear defects. While school and public health nurses often do routine screening, the children screened are generally at an age when even if discovered, many defects can no longer be corrected.

The lack of an adequate mechanism for the detection of vision and hearing defects in pre-school children prompted the establishment of the Pre-School Medical Survey of Vision and Hearing, a public service organization sponsored by the Minnesota State Medical Association. The Survey is unique in that screening of the pre-school children is done by medically-trained, but non-professional, volunteers. Various volunteer organizations have cooperated with the Survey in providing screening in their communities. Men's organizations often sponsor the program financially while the woman's groups do the actual screening. The Women's Auxiliary of the Minnesota State Medical Association has proved to be particularly effective in promoting the Survey throughout the state.

The screeners for the Survey are trained by volunteer demonstrators through the use of medically edited films, demonstration of the techniques used, and by practice sessions with kindergarten children. At present there are nineteen women who have qualified to train volunteer screeners for the Survey through a training course at the University Hospitals, as well as firsthand experience in screening.

The emphasis of the Survey is entirely medical. No volunteer organization is allowed to conduct a screening unless it agrees to abide by the medical directives of the Board of Directors of the Survey. Endorsement of the Survey is sought from the county medical society, and all physicians in the community are informed of the purpose of the Survey. If a child has a suspected hearing or vision defect, he is referred to his family physician or a medical specialist. (The screeners, however, do not recommend any particular doctor.)

The Pre-School Survey is a multi-purpose organization. One of its prime objectives is to promote parent and community education in vision and hearing health. In each community in which the Survey is conducted, an intense effort is made to reach the families of four-years-olds with information about the importance of screening and a request for

Continued

cooperation. Leaflets have been prepared for distribution to the parents at the time of screening. These are written in carefully worded, non-technical language and explain the importance of good ear and eye health.

Special leaflets which explain the nature of the child's defect are given to the parents of those children who are referred to a physician for examination. The volunteer screeners do not answer medical questions from their own knowledge. They are instructed to have the parents consult their family physician if the answers to their questions cannot be found in the literature. Local newspapers are widely used to inform the community of the nature and purpose of the Survey.

How does the volunteer screener test the four-year-old child? At this age, the child's senses are not fully developed. He has not had the educational or social training for understanding and cooperating with the screening techniques. His attention span is short. Through experience, the Survey has developed special techniques for working with such young children.

The screening tests are introduced to the children as games. Local sponsors of the Survey are urged to publish a picture of the Snellen E, which is used to test visual acuity, in their newspapers. In advance publicity, parents are asked to teach their children the "E game" in which the child indicates the position of the E with a hand or finger. The ushers at the screening center also teach the waiting children a game using the picture board from the hearing screening device so that they will be familiar with this screening technique.

Besides testing visual acuity, the screeners also check for muscle imbalance using a flashlight and an occluder. Any child whose eyes exhibit a constant deviation or a suspected tendency to deviate is referred for examination. Criteria for referral of children for medical examination have been carefully determined. Any child who is unable to read half of the 20/40 symbols with either eye or who has a visual discrepancy between the right and left eye of more than one chart line is referred for examination. The screeners are also instructed to refer children with any other signs which may indicate eye trouble, such as red or crusted lids or eyeballs.

Because the volunteer screener would be

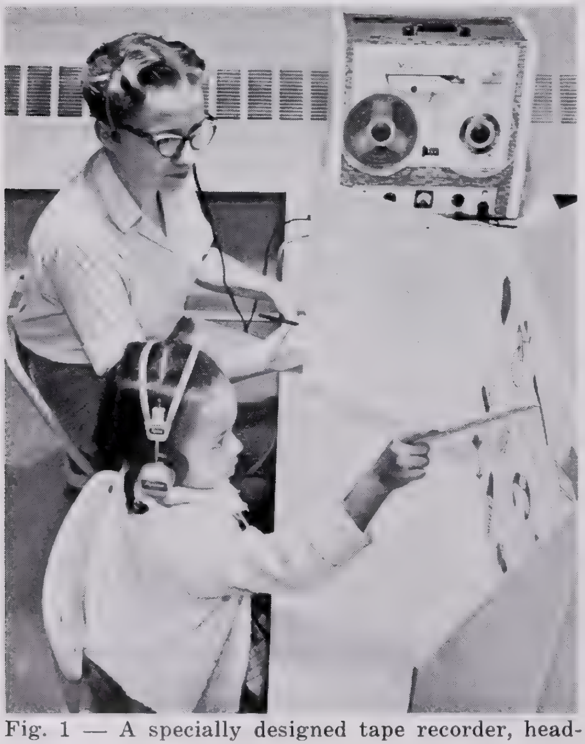

Fig. 1 — A specially designed tape recorder, headphones, and the picture screen comprise the equipment for the Visual Auditory Screen for Children.

Fig. 2 — There was no apparent evidence that this child used only one eye.

unable to conduct a reliable test with the puretone audiometer and the efficacy of a questionnaire answered by the parents is doubtful, special equipment is necessary for use in hearing screening of pre-school children. A group of audiologists under the direction of Dr. K. M. Simonton has developed a screening device called the Visual Auditory Screen for Children, or VASC.

Testing two children simultaneously, the screeners do not attempt to make a precise measurement of hearing with the VASC machine. In most cases, however, the machine will detect a hearing loss within a range from slight to severe.

The child being tested is seated before the test board on which pictures of familiar objects are mounted at random (See Figure 1). Through the earphones, he hears a series of twelve words with each ear and is asked to point to the picture of the object mentioned. Each ear is tested separately, and the screener, seated behind the child, is able to hear the tape and score the child as he takes the test. The intensity of the tape is decreased in predetermined steps from a level of 51 decibels to 15 decibels. The child's ability to hear the tape closely approximates his ability to hear normal conversation, and any child who successively misses several words or who misses two of the last three words at the 15 Db. level fails the test and is referred. When a child is referred for examination, the parent is given a referral card addressed to the physician with the option to return for rescreening if desired.

A perusal of Table 1. indicates the growth of the Survey during its five-year history. Beginning with screening in two communities in 1961, the Survey covered sixty-one towns in 1963. This year seventy-two surveys are already planned.

The table also indicates one of the major difficulties encountered by the Survey — the follow-up on children referred for examination. Approximately 50% of the medical reports have been returned to the Survey Headquarters. It is known that more action is taken on referrals, but medical reports are in many cases mislaid or forgotten. Thus figures on positive reports are conservative. Because these statistics do not give an accurate picture of the work of the Survey, the Board of Directors has decided that, beginning in 1966, records will be kept of all known action taken on referrals whether or not a signed medical report is received.

The physician in the community in which there is a survey can be of great assistance. He is in a position to encourage his patients to cooperate with the Survey and to follow the recommendations of the screeners. Occasionally there is a false positive report. It is important for the physician to be able to interpret the necessity of the survey even in cases of a false positive report. The value in identifying a potentially crippling defect in one child far outweighs the inconvenience to the parent of a child who has been mistakenly referred.

A 16 mm. informational film is available for loan from the Survey Headquarters. This

TABLE I
Report of the Pre-School Medical Survey of Vision and Hearing

*Medical reports from fall, 1965, will be coming in throughout the next six months. The figures given for 1965 and the five-year total are accurate as of March 8, 1966.

Continued

is an excellent introduction to the Survey for both the medical profession and volunteer organizations which may wish to sponsor screening.

The value of the Survey is quite evident. The files of the Pre-School Medical Survey of Vision and Hearing are filled with case histories of children who have been helped as a result of early detection through screening.

Case Reports

Case 1

Routine vision screening carried on by medically-trained volunteers in the spring of 1965 in a PTA-sponsored survey in cooperation with the Pre-School Medical Survey, revealed that this child, who appeared entirely normal, relied entirely on one eye (See Figure 2). Medical examination showed a tiny cataract had caused him to avoid use of the eye and vision simply did not develop. Surgery was considered, but not advised at that time. However, the immediate need was to force the development of vision by use, inspite of the obstruction. Thus the better eye was patched. Results have not yet been assessed, but the potential for useful vision will remain, having been fostered at the only age (before six) when this could be done.

Case 2

A five-year-old boy seemed to the kindergarten teacher to be "slow," and she asked the counselor to test him. He was assigned tentatively an IQ of 51. He repeated kindergarten. His speech improved little, but he went into the first grade on trial. The school nurse giving a routine eye test, thought she detected signs that he did not hear when he could not see her face. Her test with the puretone audiometer seemed implausible. She repeated it several times and finally reported a suspected hearing loss to the parents. The otolaryngologist found a loss of around 70% in one ear and 28% in the other. The child was a candidate for a hearing aid, but this was refused unless the child's educational program was revised more in line with his needs. The audiologist stressed that the mental retardation assumption was just plain wrong. He pointed out that the boy had used self-taught lip-reading to "get by" three separate teachers, none of whom suspected his hearing loss. The school agreed to give speech teaching by a specialist, academic coaching, and to hire a special tester to make the estimation of academic potential again with tests appropriate to individuals with hearing loss. The child received a hearing aid. At last report, he was forging ahead, but there was much lost ground to make up academically and with respect to speech. The best news was the improvement in his emotional adjustment to school. Had this child's hearing loss been detected by screening at age four, it is quite probable that his IQ, now determined in the neighborhood of 100, would never have been so underestimated, he need not have repeated kindergarten, and the damage to his morale would have been greatly lessened. Chances are that his speech problems would have been much less severe.

From cases documented by the Survey, one can see that in many instances even the conscientious parent or teacher does not notice that Johnny or Jane does not see or hear well. Symptomatic behavior may be attributed to some other cause, or to a certain extent, the child may have accommodated himself to his limitations. The Pre-School Medical Survey of Vision and Hearing has provided the medical profession with a valuable tool for preventing crippling loss of sight and hearing among the children of Minnesota. With the cooperation of volunteer screeners, parents, and the medical profession, the Survey will become increasingly more effective in serving the people of the State.

Acknowledgment

When it comes time to express appreciation for a wonderful job done, particularly when many many volunteers have given so much of their time and effort, it is usually very difficult to single out any one individual for outstanding service. However, Mrs. John B. Stoltze, who has so capably served as Executive Secretary to the Pre-School Medical Survey of Vision and Hearing since its inception in 1961, richly deserves the credit for spark-plugging this organization from its infancy to its present growth. She has worked untiringly, sometimes against great odds and discouragement, and she has succeeded not only in organizing the work itself, but in rendering a real service to the younger generation in Minnesota. The members of the Minnesota State Medical Association wish to express their sincere appreciation to Mrs. Stoltze for a job very well done.

Medical Missionary Program

The American Medical Association's 115th Annual Convention in Chicago June 26-30, will feature a series of programs, over a four-day period. The AMA Department of Medicine and Religion is focusing attention on the programs in recognition of the recent increased involvement of American physicians in world-wide humanitarian work. Special Sessions: The programs will be of interest to the physician who donates his time and skill to medical missionary work on a short-time basis, as well as those who devote extended periods of time or their careers to such work.

Southeast Asia: On Monday, June 27, the medical missionaries will be able to attend the meeting of the AMA's Section on Military Medicine. On Wednesday, June 29, a special reception will be held for medical missionaries and those interested in the medical missionary field.

Physician's Diary

False friends are like our shadow, keeping close to us while we walk in the sunshine, but leaving us the instant we cross into the shade. — Bovee

Dr. D. W. Feigal, Wayzata, has been elected president of the Hennepin County Academy of General Practitioners, and **Dr. M. B. Divertie** of the Mayo Clinic is the new president-elect of the Rochester Rotary Club.

* * *

Dr. F. N. Grose was recently honored for ten years of service at St. John's Hospital at Browerville. An open house was given to celebrate the occasion.

* * *

Dr. and Mrs. V. M. Johnson of Dawson were honored recently by the residents of that community on occasion of their 25th wedding anniversary.

* * *

Dr. Murray H. Hunter of Farmington has been elected to active membership in the Academy of General Practice, and **Dr. George O. Hilgermann** of Wayzata has been elected to a fellowship in the American College of Surgeons.

* * *

NEW LOCATIONS . . . **Dr. John R. Fisher** will leave Blooming Prairie for additional training at the Washington University School of Medicine in St. Louis, Missouri . . . **Dr. Charles I. Benjamin** will be associated with **Dr. Gordon E. Lee** in the Lee Clinic in Glenwood . . . **Dr. Orville P. Swenson** of Carlton has left for active duty with the armed forces . . . **Dr. Lawrence Boies, Jr.** is practicing medicine in the Wayzata Medical Building . . . **Dr. Victor M. Colago** will start practicing medicine at the Browns Valley Community Clinic . . . **Dr. Leo Grieben** joined the Hastings State Hospital staff in January.

* * *

Dr. Norman W. Hoover and **Dr. Thomas P. Comer** of Rochester, **Dr. Matthew J. Wier** of Virginia and **Dr. Perry H. Engstrom** of Wheaton have volunteered for Project Viet-Nam. Doctors will work in provincial hospitals in various sections of Viet-Nam, where they will minister to sick and wounded Vietnamese civilians.

* * *

Dr. E. E. Zemke of Fairmont has been elected chief-of-staff of the Fairmont Community Hospital, and **Dr. Robert Zemke** will serve as secretary-treasurer. **Dr. William Feigal** has been named vice president.

* * *

Dr. Owings W. Kincaid of Rochester has been elected a fellow of the American College of Radiology.

* * *

Dr. James Janecek, an asistant professor of psychiatry at the University of Minnesota hospitals, has joined the St. Paul-Ramsey hospital staff in psychiatry. He will be director of the in-patient service.

* * *

Dr. Victor Johnson, director of the Mayo Graduate School of Medicine for the past 18 years, and **Dr. Gershom J. Thompson**, noted Mayo Clinic urologist and cancer specialist, are retiring from the Mayo Clinic. **Dr. and Mrs. Johnson** plan to move to the Island of Majorca in the Mediterranean; however, **Dr. Thompson** has no definite plans for the immediate future.

* * *

Five new staff physicians joined the Mayo Clinic in April. They are: **Doctors Ronald F. Kettering, Robert V. Groover, Colum A. Gorman, Paul Didisheim** and **Richard A. De Remee.**

* * *

Dr. C. A. Anderson of Hector recently attended a post-graduate course in medicine at Fort Lauderdale, Florida.

* * *

Dr. David Halvorson of Northfield is the newly elected president of the Rice County Medical Society. Other officers are: **Dr. Richard Meyer** of Faribault, vice-president, and **Dr. Richard Searl** of Faribault, secretary.

* * *

Dr. Harry J. Smith of Lake Crystal was recently elected head of general practice of the Immanuel Hospital in Mankato. **Dr. B. N. Batdorf** of Mankato is the new president, and **Dr. D. E. Flentje** of Mankato is the new vice-president.

This "case history" runs to some 10,000 pages

This is a typical "case history" of one new drug – or, rather, a proposed new drug – assembled for submission to the U.S. Federal Food and Drug Administration. These volumes are the result of several years' work by thousands of professional and skilled personnel in just one pharmaceutical company's research laboratories, and by hundreds of physicians in medical schools, hospitals, and private practice. They cover every aspect of experience with this proposed new agent from chemical laboratory to clinic, from mouse to man. Each volume could conceivably represent hundreds of thousands of dollars of financial investment, countless hours of human effort. This veritable mountain of data stands behind every new agent offered to you by pharmaceutical manufacturers – a reassuring testimonial to the efficacy, safety and purity of the drugs you will prescribe today to lower the cost of disease to your patients.

Pharmaceutical Advertising Council
1155 Fifteenth St., N. W., Washington, D.C. 20005

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

Medical Economics

Partnership Retirement

Without a separate and specific investment plan funding the retirement program, it is not economically sound. We do not think that retirement of a partner should ever be funded out of current and future income of the remaining partners. Beyond a retiring doctor's equity in physical assets and partnership accounts, any payments to him for retirement should be funded by some investment program and based upon that doctor's specific equity or contributions to the fund.

In our opinion, any attempt to support retirement out of the future earnings of remaining partners ranges from financially dangerous to impossible. Under ideal circumstances of constantly rising income such a plan might be supportable but would still be illogical. If income is increasing it is coming from the increased efforts and heavier work-load of the remaining doctors. To pay out a portion or all of this increase to a retired member would certainly be an injustice to the producing doctors. Like our Social Security system, such a plan under proper circumstances might be supportable on sheer volume of dollars, but it would be completely illogical on economic and moral grounds.

In a recent issue of MEDICAL ECONOMICS, a writer advocated such a plan under the caption, "Let Your Partners Pay For Your Retirement." This article advocated just what the title implies and dwelled exclusively on the possibility of such a plan, ignoring completely any justification for such a plan.

The plan advocated in that article made many erroneous assumptions. Two were most flagrant: (1) that the number of partners would increase constantly, and (2) that the per-doctor income would continue to rise constantly.

Conceding these two premises, it is possible that the plan might function. However, should the profits decline and/or the number of partners decrease, a financial impossibility could result. Another unsound premise involved was the forfeiture of capital and accounts by a doctor leaving voluntarily for reasons other than death or retirement. To summarize: such a plan's success would be solely dependent upon completely favorable financial circumstances; adverse practice and economic conditions could render it wholly unsupportable, except to the ruinous detriment of the remaining partners.

In considering the feasibility of such proposals, you must place yourself in the position of both the retiring and the remaining partner and consider all contingent adversities. If the plan can survive such a test, it may warrant further consideration.

If we agree on the basic premise that a plan must be founded by an investment program and the retiring doctor's contribution to the program, the remaining question is: should such a plan be an individual or a collective responsibility.

In our opinion, unless some specific financial or tax advantage presents itself, partners should provide their own retirement through their individual investment plans. The major problem of a partnership plan is agreeing upon a common medium for investment and the amount to be designated for this purpose. The senior doctors may lean toward an annuity plan with heavy dollar commitments, while younger doctors with already heavy financial burdens would favor a stock or fund purchase plan with lower contributions.

If a tax benefit can be realized, certainly a compromise should be reached, but we would all agree on the imprudence of compromising a financial plan if no such advantage exists. In the absence of this tax advantage, certainly each doctor should pursue his own financial goals.

What are the potential tax benefits available. The prospects of a corporation or association for the two-to-four-man group appear dimmer than at any time in the past. This leaves the Self-Employed Retirement Plan which presently offers only a minimum tax advantage. If and as the law on these plans becomes more favorable, the logic for such plans will increase. However, under present law, these plans offer only a small advantage to those in the right financial situation.

Bamadex® Sequels®

Contraindications: In hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised; especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of pre-existing symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dose—operation of motor vehicles, machinery or other activity requiring alertness should be avoided. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness.

Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia, the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor, and respiratory collapse.

Sustained circulatory, respirator
and cerebral stimulation for th

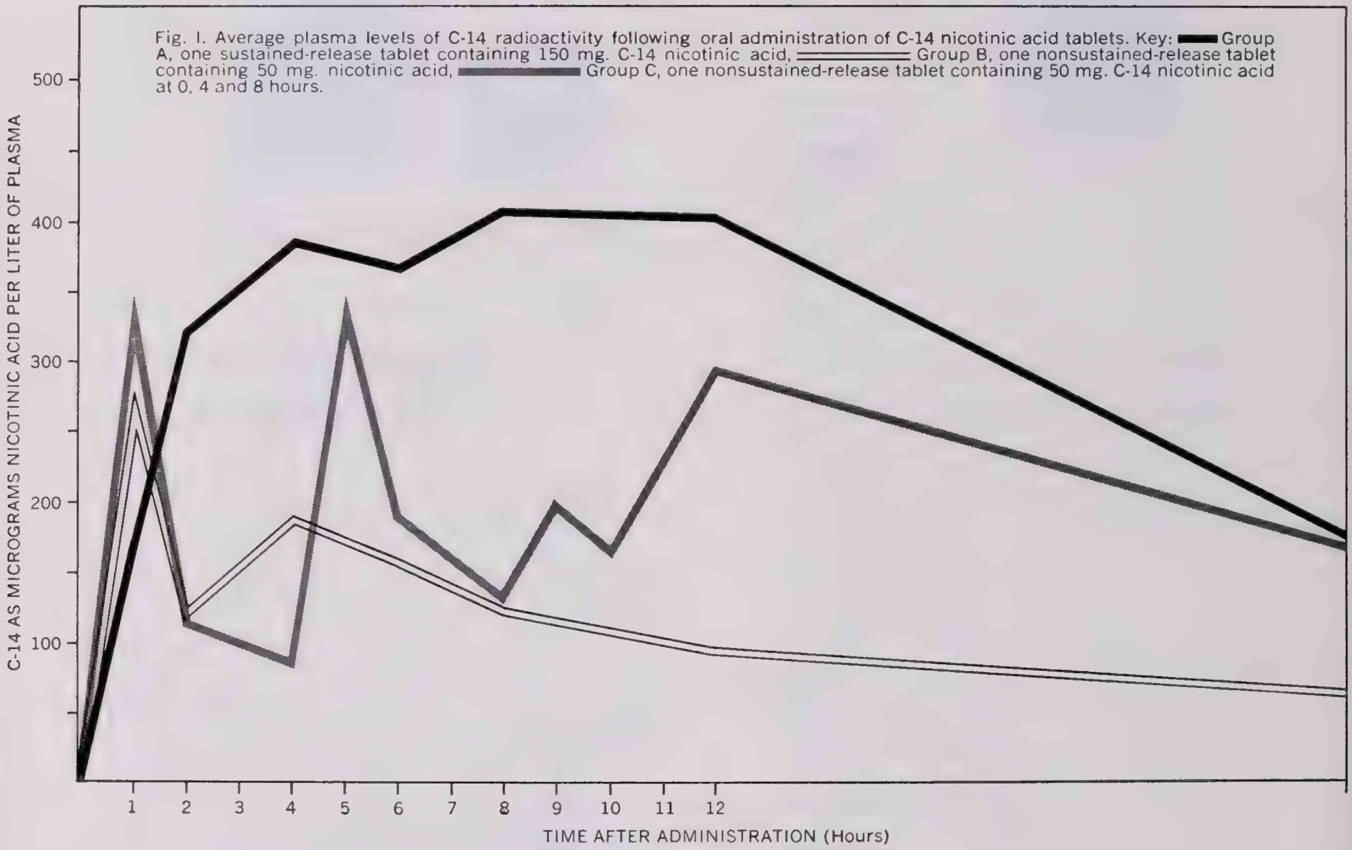

Fig. I. Average plasma levels of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ▬ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═ Group B, one nonsustained-release tablet containing 50 mg. nicotinic acid, ▬ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

(fewer absent doses by absent-minded patients)

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

ged and debilitated

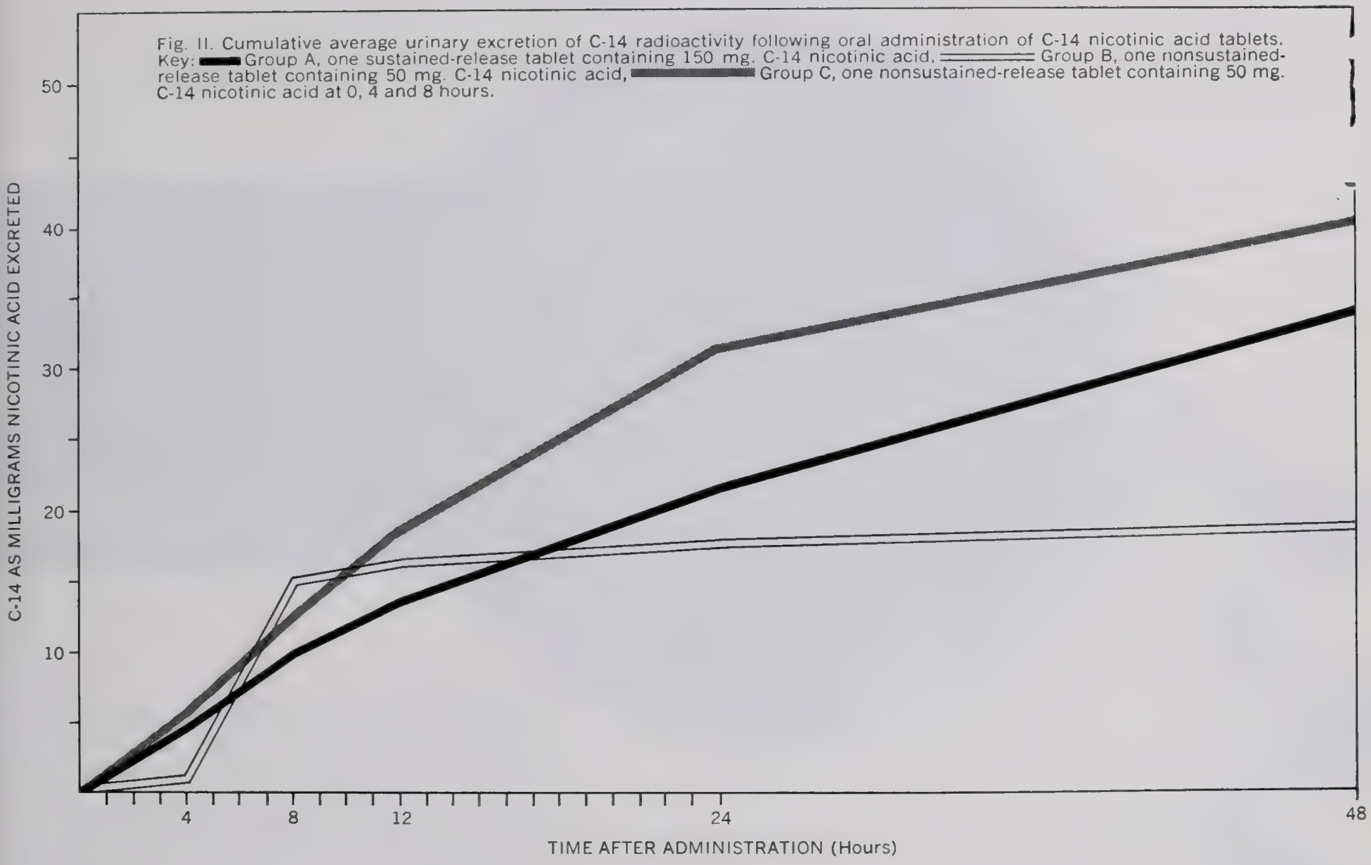

Fig. II. Cumulative average urinary excretion of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ▬ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═ Group B, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid, ▬ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

Tempotrol® Time Controlled Tablet

When uncontrolled diarrhea brings a call for help

When the diarrhea sufferer has run the gamut of home remedies without success, pleasant-tasting CREMOMYCIN can answer the call for help. It can be counted on to consolidate fluid stools, soothe intestinal inflammation, inhibit enteric pathogens, and detoxify putrefactive materials — usually within a few hours.

CREMOMYCIN combines the bacteriostatic agents, succinylsulfathiazole and neomycin, with the adsorbent and protective demulcents, kaolin and pectin, for comprehensive control of diarrhea.

INDICATIONS: Diarrhea.

CONTRAINDICATIONS: Do not use in intestinal obstruction, extensive ulceration of bowel, or diverticulosis; in hypersensitivity to sulfonamides or neomycin; in pregnancy at term, in premature infants, or during first week of life in the newborn.

WARNINGS: Use only after critical appraisal in patients with hepatic or renal damage, urinary obstruction, or blood dyscrasias. Fatal hypersensitivity reactions and blood dyscrasias reported with use of sulfonamides. Consider periodic blood counts, hepatic and renal function tests during intermittent or chronic use.

PRECAUTIONS: Succinylsulfathiazole: Use with caution if there is history of significant allergies and/or asthma. Continued use requires supplementary vitamins B_1 and K. *Neomycin:* Watch for

your ℞ for
Cremomycin
can provide relief

curare-like neuromuscular block during anesthesia if neomycin is used preoperatively in large doses when renal function is poor; watch for overgrowth of nonsusceptible organisms. Consider possibility of ototoxicity and nephrotoxicity with prolonged high dosage.

SIDE EFFECTS: As with all sulfonamides: Headache, malaise, anorexia, G.I. symptoms, hepatitis, pancreatitis, blood dyscrasias, neuropathy, drug fever, rash, conjunctival and scleral injection, petechiae, purpura, hematuria, and crystalluria have been noted. Reduced fecal output of thiamine and decreased synthesis of vitamin K have been reported. *Neomycin:* Nausea, loose stools.

Before prescribing or administering, read package circular with product or available on request.

Alertonic®

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B_1) (10 MDR*), 10 mg.; riboflavin (vitamin B_2) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B_6), 1 mg.; niacinamide (5 MDR), 50 mg.; choline†, 100 mg.; inositol†, 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.
†The need for these substances in human nutrition has not been established.

the need for a tonic knows no age

Life *can* begin at forty—except when functional fatigue causes her to feel tired all the time; to start losing interest in friends and surroundings; to look and act older than her years. Alertonic—*a prescription tonic*—can help your patient become her normal self again. Alertonic helps relieve mild depression, revive interest and restore purposeful activity promptly...with a formula that is efficient *and* economical. Alertonic contains a mild central stimulant (pipradrol hydrochloride), 15% alcohol, essential vitamins and minerals. No hormones or MAO-inhibiting drugs are included. No iron. No iodine. One pleasant-tasting tablespoonful before each meal comprises the usual daily dose.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Contraindications: As with other drugs with CNS-stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive-compulsive states.

Side Effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

Merrell

now...introducing a new high-strength dosage fo

SIGNEM

A 'MAXIMUM SECURITY' ANTIBIOTIC*

- * THE BROAD RANGE DEPENDABILITY OF TETRACYCLINE
  long established as the broad-spectrum agent of first choice in a wide variety of infections
- * WITH THE ADDED SECURITY OF MEDIUM-SPECTRUM REINFORCEMENT
  triacetyloleandomycin is highly active against the common 'coccal' pathogens, including certain strains of staphylococci resistant to penicillin and tetracycline
- * ESPECIALLY VALUABLE IN U.R.I.
  provides decisive therapy in acute respiratory infections and other conditions in which staphylococci, streptococci or mixed flora are frequently encountered
- * NOW AVAILABLE IN NEW STRENGTH FOR NEW CONVENIENCE AND ECONOMY
  Signemycin 375—high-potency capsules for simpler administration, greater patient economy

YCIN® 375

(tetracycline 250 mg.
triacetyloleandomycin 125 mg.)

Indications: Indicated in the therapy of acute severe infections caused by susceptible organisms and primarily by bacteria more sensitive to the combination than to either component alone. In any infection in which the patient can be expected to respond to a single antibiotic, the combination is not recommended. Signemycin should not be used where a bacteriologically more effective or less toxic agent is available. *Triacetyloleandomycin, a constituent of Signemycin, has been associated with deleterious changes in liver function.* See precautions and adverse reactions.

Contraindications: Contraindicated in individuals who have shown hypersensitivity to any of its components. Not recommended for prophylaxis or in the management of infectious processes which may require more than 10 days of continuous therapy. If clinical judgement dictates therapy for longer periods, serial monitoring of liver function is recommended. Not recommended for subjects who have shown abnormal liver function tests, or hepatotoxic reactions to triacetyloleandomycin.

Precautions and Adverse Reactions: Triacetyloleandomycin, administered to adults in daily oral doses of 1.0 gm. for 10 or more days, may produce hepatic dysfunction and jaundice. Adults requiring 3 gm. of Signemycin initially should have liver function followed carefully and the dosage should be reduced as promptly as possible to the usual recommended range of 1.0 to 2.0 gm. per day. Present clinical experience indicates that the observed changes in liver function are reversible after discontinuation of the drug. Use with caution in lower than usual doses in cases with renal impairment to avoid accumulation of tetracycline and possible liver toxicity. If therapy is prolonged under such circumstances, tetracycline serum levels may be advisable. In long term therapy or with intensive treatment or in known or suspected renal dysfunction, periodic laboratory evaluation of the hematopoietic, renal and hepatic systems should be done. Formation of an apparently harmless calcium complex with tetracycline in any bone forming tissue may occur. Use of tetracycline during tooth development (3rd trimester of pregnancy, infancy and early childhood) may cause discoloration of the teeth. Reversible increased intracranial pressure due to an unknown mechanism has been observed occasionally in infants receiving tetracycline. Glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and definite allergic reactions occur rarely. Severe anaphylactoid reactions have been reported as due to triacetyloleandomycin. Photosensitivity and photoallergic reactions (due to the tetracycline) occur rarely. Medication should be discontinued when evidence of significant adverse side effects or reaction is present. Patients should be carefully observed for evidence of overgrowth of nonsusceptible organisms including fungi, which occurs occasionally, and which indicates this drug should be discontinued and appropriate therapy instituted. Steps should be taken to avoid masking syphilis when treating gonorrhea.

Minnesota Medicine at a Glance

Primary Aldosteronism Unmasked — Hawley and Tobian Page 889

A case report of aldosteronism due to adrenal cortical adenoma, in which the clinical symptoms and metabolic alkalosis became evident with the administration of thiazid, points out the possible clinical value of the drug in unmasking an otherwise undiagnosable disease of the adrenal gland.

Hormone-secreting adrenal adenomas may have a variety of histologic appearances and their hormonal functions may be difficult to recognize under the microscope. These tumors can be analyzed for hormone, but the content of the adenoma may not reflect its secretory ability in vivo.

In that the clinical manifestations of primary aldosteronism are usually vague, unless accelerated potassium depletion is effected, the use of thiazide diuretic, as in this instance, will accelerate the potassium depletion and make the diagnosis more evident.

Though the removal of the adrenal tumor effected improvement in the chronic potassium depletion, it did not appreciably affect the hypertension, which was then thought to represent a metacorticoid hypertension similar to that which has been observed in the rat receiving desoxycorticosterone and salt over a long period of time.

Pseudomembranous Enterocolitis — Strickler and Rice Page 899

A review of the literature is presented on pseudomembranous enterocolitis and many associated or related conditions. Staphylococcal enterocolitis is found to be frequently considered as the same disease; but the authors find and record considerable evidence from their review of literature that indicates a definite difference. In essence, staphylococcal enterocolitis may at times produce a pseudomembrane and thus appear similar to pseudomembranous enterocolitis. However, several specific differences in the two conditions are enumerated by the authors.

The case described in this paper, because of its bacteriologic features showing predominantly staphylococci, could be classified in either category. The major point of presentation in this case of advanced pseudomembrane and necrosis is the temporary salvage of the patient by extirpative surgery of nearly all of the colon. Most classical staphylococcic enteritis cases do not advance to this point and are amenable to antibiotic therapy.

Amputation Site — Wessman Page 905

After amputation of a lower extremity the circulation of the stump is subject to the same problems as that of the contralateral extremity. In determining the site of amputation, it is significant that a doctor should make an evaluation of the circulation in the extremity to be amputated, in order for it to be able to tolerate a prosthesis or any other stress that will be applied to it when healing is complete.

When adequate collateral circulation is available below the knee there has usually been a slow onset of the disease process; but when there is an absence of general pulsation, which is frequently observed in patients with cardiac lesions, the collateral circulation has not had time to develop, and an amputation is then indicated above the knee.

Oscillometry, skin thermometry, angiography, and plethysmography are tests that can be made to provide an evaluation of the circulation. Each of these has its special value.

Vision Interference Indicator — Garner and Fulghum Page 909

The authors describe a training device for instructing in the use of the tonometer for measuring intraocular tension. The trainee learns to position himself so that the patient can maintain fixation during measurement of intraocular tension.

Anemia Causing Heart Failure — Searl & Speckhals Page 911

Though iron deficiency anemia is not uncommon in infants, myocardial decompensation resulting from this type of anemia is observed less often. It should be watched for in premature infants showing a rapid growth rate, and when the hemoglobin is found to be at a level of 5 grams, urgent medical measures should be instituted before restoring packed red cells into the circulation.

The response of hemoglobin and reticulocyte count to oral iron therapy is illustrated in the accompanying graph.

Cerebral Vascular Malformation — Neurological Conference Page 961

The case history of a young man with an arterial venous malformation was thoroughly evaluated from all standpoints. After this patient had become stabilized, a successful craniotomy and removal of the arterial venous malformation resulted in his part-time rehabilitation. The interesting details of this case and a complete analysis are reviewed in the neurologic conference.

Servus Naturae

A physician should be the servant of Nature, not her enemy; he should be able to guide and direct her in her struggle for life, and not, by his unreasonable influence, throw fresh obstacles in the way of recovery. . . . The knowledge of Nature is the foundation of the science of medicine.

If you wish to be a true physician you must be able to do your own thinking, and not merely employ the thoughts of others.

The patient must not be out of the physician's mind day or night. He must put his whole power of reasoning and his judgment deliberately in the service of his patients. — Paracelsus (1493-1541)

Traffic

There is never any traffic congestion on the straight and narrow path.

Blood-glucose screening for all your patients?

...because "Abnormalities of glucose metabolism are among the [most common] encountered in clinical practice...."* Simple, quick, economical blood-glucose screening with DEXTROSTIX® Reagent Strips is practicable in every regular physical examination, emergency situation, and whenever hypo- or hyperglycemia may be of clinical significance—for "The precision and accuracy of DEXTROSTIX ...meet the need for an always available simple screening method...."* All that is required for screening with DEXTROSTIX is 60 seconds and a globular drop of capillary or venous blood. Abnormal readings will be a valuable aid to diagnosis; normals will help you establish an important baseline for future reference.

Marks, V., and Dawson, A.: Brit. M. J. *1*:293, 1965.

DEXTROSTIX—
provides a clinically useful determination when performed according to directions†

DEXTROSTIX is not intended to replace he more precise analytical laboratory methods.

Yes—all your patients

for The Age of Anxiety

For those who cannot cope realistically with the emotional turmoil and stress of modern living, the physician has at hand many valuable psychotherapeutic aids. One of the most useful is Librium, a pre-eminent prescription for excessive anxiety in this modern age.

LIBRIUM® (chlordiazepoxide HCl)

5 mg 10 mg 25 mg capsules in #50's

ROCHE

In prescribing: Dosage—Adults: Mild to moderate anxiety and tension, 5 or 10 mg t.i.d. or q.i.d.; severe states, 20 or 25 mg t.i.d. or q.i.d. Geriatric patients: 5 mg b.i.d. to q.i.d. **Side Effects:** Side effects, usually dose-related, include drowsiness, ataxia, minor skin rashes, edema, menstrual irregularities, nausea and constipation. When treatment is protracted, blood counts and liver function tests are advisable. Paradoxical reactions may occasionally occur in psychiatric patients. Individual maintenance dosages should be determined. **Precautions:** Advise patients against possibly hazardous procedures until maintenance dosage is established. Though compatible with most drugs, use care in combining with other psychotropics, particularly MAO inhibitors or phenothiazines; warn patients of possible combined effects with alcohol. Observe usual precautions in impaired renal or hepatic function, in long-term treatment and in presence of depression or suicidal tendencies. Exercise caution in administering drug to addiction-prone patients or those who might increase dosage; withdrawal symptoms, similar to those seen with barbiturates or meprobamate, can occur upon abrupt cessation after prolonged overdosage. Caution should be exercised in prescribing any therapeutic agent for pregnant patients. **Supplied:** Capsules, 5 mg, 10 mg and 25 mg, bottles of 50.

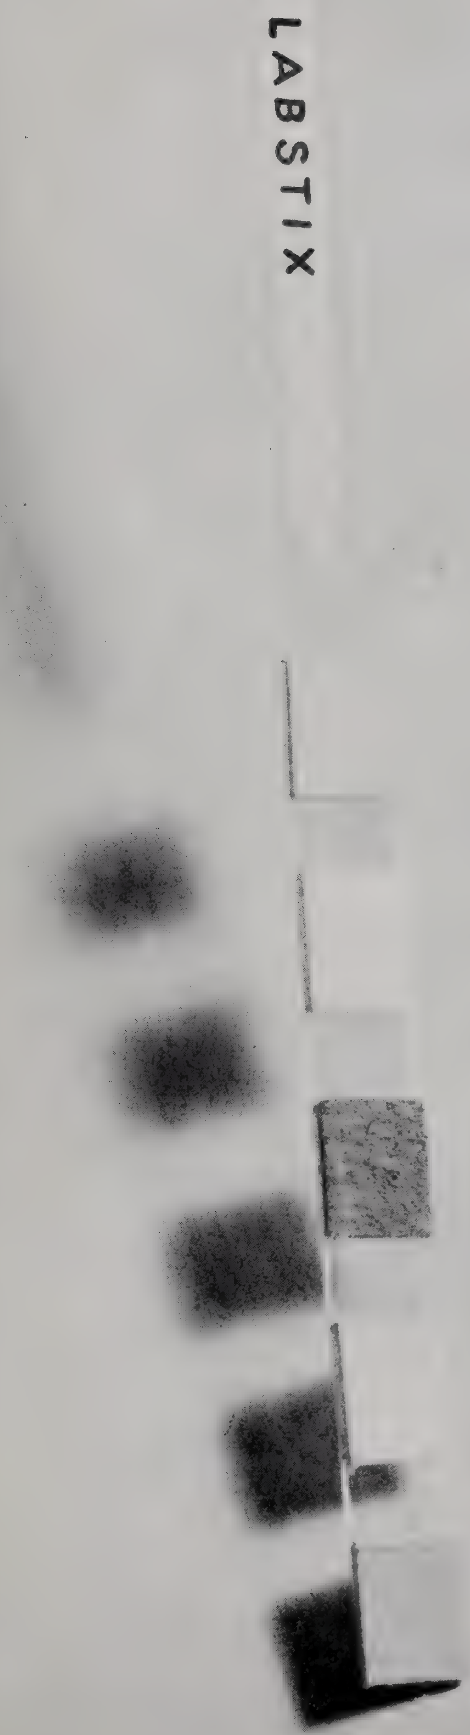
new from Ames 5 basic uro-analytical facts in 30 seconds



Labstix®

BRAND REAGENT STRIPS

...broadest urine screening possible from a single reagent strip

Urine test results with LABSTIX Reagent Strips can represent significant guides to differential diagnosis or therapy in many conditions. An unexpected "positive" may enable you to detect hidden pathology—long before more recognizable symptoms become evident. Negative results, which permit you to rule out abnormalities in a broad clinical range, can serve as baseline values for reference in future examinations. The 5 colorimetric test areas encompassed on LABSTIX Reagent Strips are:

pH—values are read numerically in the essential range of pH 5 to pH 9.

Protein—results are read either in the "plus" system or in mg. % in amounts approximating "trace," 30, 100, 300, and over 1000 mg. %.

Glucose—provides a "Yes-or-No" answer for urine "sugar spill."

Ketones—detects ketone bodies in urine—**both** acetoacetic acid and acetone. Reacts with as little as 5 to 10 mg. % of acetoacetic acid.

Occult Blood—specific test for intact red cells, hemoglobin or myoglobin. Results are read as negative, small, moderate or large amounts.

Now a Clear Reagent Strip of Firm Construction

...facilitates handling during testing procedure. Excellent color contrast made possible by the clear plastic strip, together with the clearly defined color charts provided, permits precise, reproducible colorimetric readings in all 5 test areas. A more definitive interpretation of uro-analytical facts is made possible.

Available: LABSTIX Reagent Strips, bottles of 100 (color charts are supplied with each bottle).

The Somatic Mask:
chest pain

heart disease or psychic tension?

"Heart symptoms"—chest pain, tachycardia, arrhythmia—invariably alarm and preoccupy the patient, though they may be completely without organic basis. Such symptoms often are somatic masks of psychic tension, arising from constant encounters with stressful situations.

When the problem is diagnosed as emotionally produced, consider Valium (diazepam) as adjunctive therapy. Valium (diazepam) acts rapidly to calm the patient, to reduce his psychic tension and relieve associated cardiovascular complaints.

Neurotic fatigue—the chronic tiredness resulting from emotional strain which so often accompanies psychogenic "heart" symptoms—also can be controlled by this highly useful agent. Valium (diazepam) often achieves results where other psychotherapeutic agents have failed.

Valium (diazepam) is generally well tolerated, and usually does not impair mental acuity or ability to function. If side effects such as ataxia and drowsiness occur, they usually disappear with dosage adjustment.

Valium®(diazepam)

2-mg, 5-mg, 10-mg tablets

In prescribing: Dosage — Adults: Mild to moderate psychoneurotic reactions, 2 to 5 mg b.i.d. or t.i.d.; severe psychoneurotic reactions, 5 to 10 mg t.i.d. or q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hrs, then 5 mg t.i.d. or q.i.d. as needed; muscle spasm with cerebral palsy or athetosis, 2 to 10 mg t.i.d. or q.i.d. Geriatric patients: 1 or 2 mg/day initially, increase gradually as needed.

Contraindications: Infants, patients with history of convulsive disorders or glaucoma.

Warning: Not of value in the treatment of psychotic patients, and should not be employed in lieu of appropriate treatment.

Precautions: Limit dosage to smallest effective amount in elderly patients (not more than 1 mg, one or two times daily) to preclude ataxia or oversedation. Advise patients against possibly hazardous procedures until correct maintenance dosage is established; driving during therapy not recommended. In general, concurrent use with other psychotropic agents is not recommended. Warn patients of possible combined effects with alcohol. Safe use in pregnancy not established. Observe usual precautions in impaired renal or hepatic function and in patients who may be suicidal; periodic blood counts and liver function tests advisable in long-term use. Cease therapy gradually.

Side Effects: Side effects (usually dose-related) are fatigue, drowsiness and ataxia. Also reported: mild nausea, dizziness, blurred vision, diplopia, headache, incontinence, slurred speech, tremor and skin rash; paradoxical reactions (excitement, depression, stimulation, sleep disturbances and hallucinations) and changes in EEG patterns. Abrupt cessation after prolonged overdosage may produce withdrawal symptoms similar to those seen with barbiturates, meprobamate and chlordiazepoxide HCl.

Supplied: Tablets, 2 mg, 5 mg and 10 mg; bottles of 50 for convenience and economy in prescribing.

A RELIABLE, PROVEN PRODUCT . . .

The BSP test, introduced in 1925, remains one of the most sensitive laboratory procedures available for determining hepatic function.

A STERILE, CONVENIENT PUT-UP . . .

Each BSP Disposable Unit contains: a sterile, glass, disposable syringe with the 5 mg./kg. BSP dosage schedule imprinted on the barrel, a sterile needle, alcohol swab and a 7.5 ml. or 10 ml. size ampule of Bromsulphalein.

The BSP unit is designed for maximum patient protection. The precalibrated syringe makes weight calculations unnecessary and provides for proper dosage regardless of patient-weight.

ECONOMICALLY PACKAGED . . .

Prepared for economic unit dispensing, this completely disposable put-up affords a savings in time and labor—the most costly commodities.

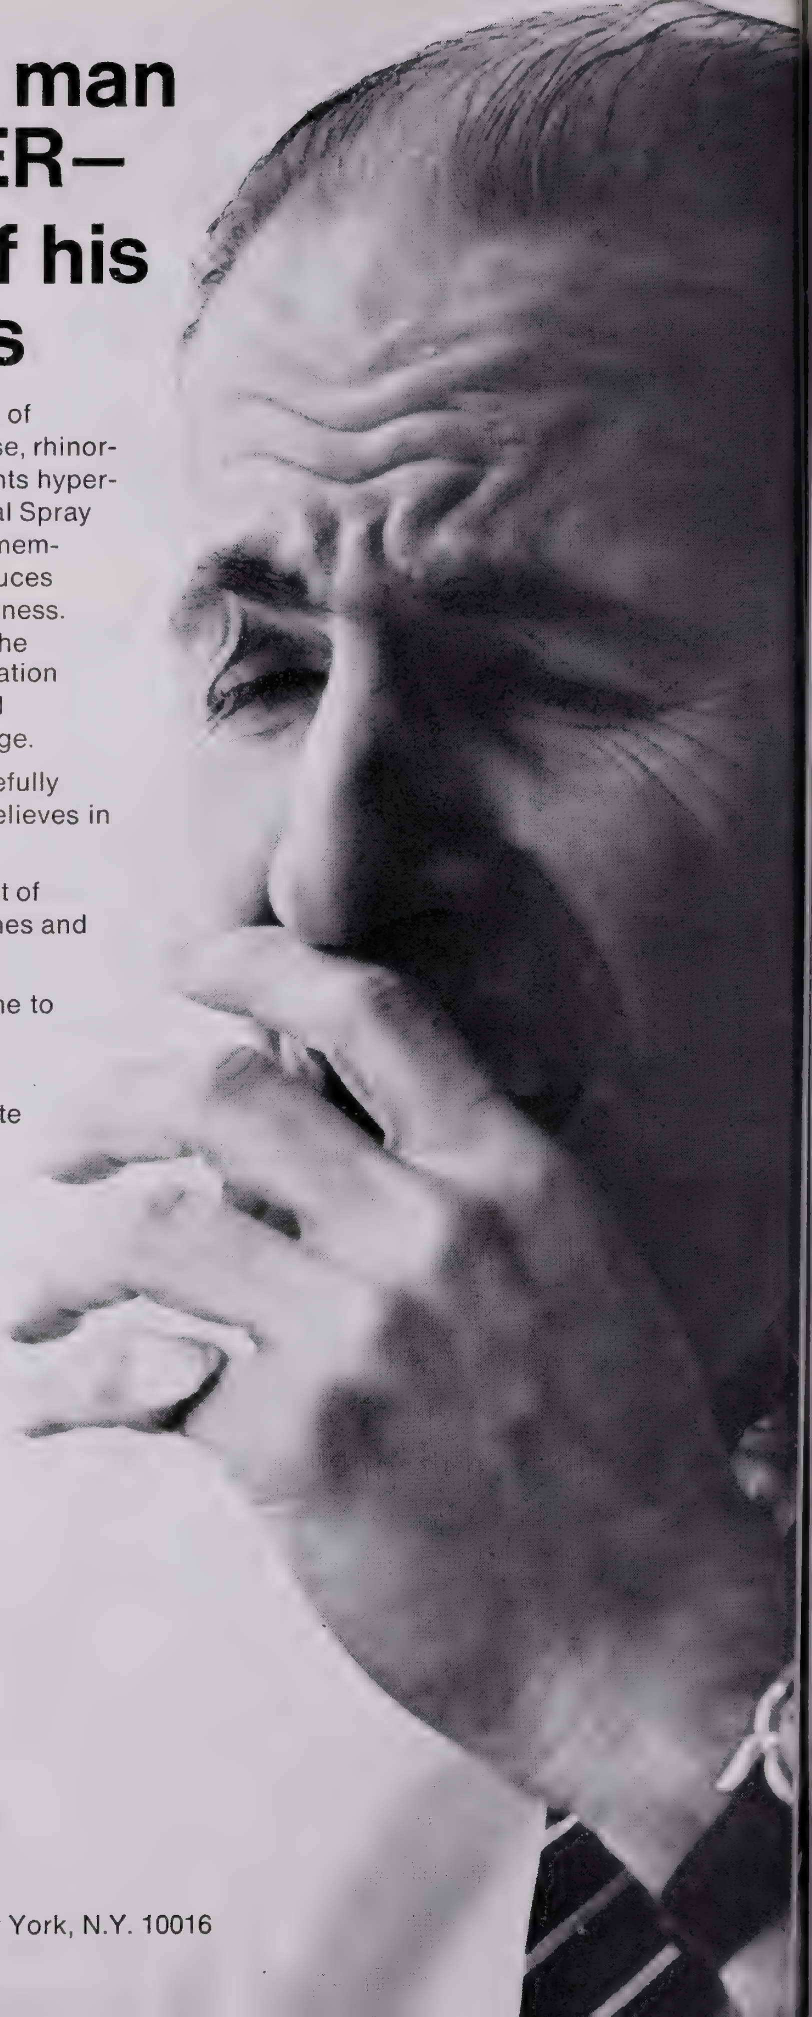
Once merely a man with HAY FEVER— now a victim of his own antibodies



Whatever term describes him in this new era of immunology, the symptoms of congested nose, rhinorrhea and sneezing haven't changed in patients hypersensitive to pollens and molds. But NTZ® Nasal Spray relieves the symptoms. It decongests nasal membranes on contact, relieves itching and reduces excessive rhinorrhea without unpleasant dryness. The first spray of well-tolerated NTZ shrinks the turbinates, helps restore normal nasal ventilation and breathing. After a few minutes, a second spray enhances sinus ventilation and drainage.

More than a simple vasoconstrictor, the carefully balanced formula of effective components relieves in three ways with:

- **N**eo-Synephrine® HCl 0.5%, a decongestant of unexcelled efficacy to shrink nasal membranes and allow more comfortable breathing.
- **T**henfadil® HCl 0.1%, a topical antihistamine to help relieve itching and rhinorrhea.
- **Z**ephiran® Cl 1:5000, an excellent wetting agent and antiseptic preservative to promote the rapid spread of components to less accessible nasal areas.

Supplied in convenient pocket-size plastic spray bottle of 20 ml. Also available as a solution of 30 ml. (1 fl. oz.) with dropper, and 473 ml. (1 pint).

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Anatomy of
Low Back Pain #1
the sedentary life
is often the seat of
low back pain

The human spine is not engineered f
prolonged sitting at desks, pianos, typ
writers and drafting boards. The stresse
set up by the heavy, forward-tilted hea
and trunk, balanced precariously on a
insufficient base, result in strain of th
dorsal musculature, particularly at th
low lumbar level.

The unusual muscle-relaxant and ana
gesic properties of 'Soma' make it espe
cially useful in the treatment of low bac
sprains and strains. 'Soma' is wide
prescribed ☐ **to relieve pain** ☐ **to rela**
muscles ☐ **to restore mobility.**

Indications: 'Soma' is useful for management o
muscle spasm, pain, and stiffness in a variety o
inflammatory, traumatic, and degenerative muscu-
loskeletal conditions. It also may act to normaliz
motor activity in certain neurologic disturbance

Contraindications: Allergic or idiosyncratic rea
tions to carisoprodol.

Precautions: 'Soma', like other central nervou
system depressants, should be used with cautio
in patients with known propensity for taking ex
cessive quantities of drugs and in patients wit
known sensitivity to compounds of similar chem
cal structure, e.g., meprobamate.

Side Effects: The only side effect reported with an
frequency is sleepiness, usually on higher tha
recommended doses. An occasional patient ma
not tolerate carisoprodol because of an individua
reaction, such as a sensation of weakness. Othe
rarely observed reactions have included dizzines
ataxia, tremor, agitation, irritability, headache, in
crease in eosinophil count, flushing of face, an
gastrointestinal symptoms.

One instance each of pancytopenia and leuko
penia, occurring when carisoprodol was admin
istered with other drugs, has been reported, as ha
an instance of fixed drug eruption with carisoprod
and subsequent cross reaction to meprobamate
Rare allergic reactions, usually mild, have include
one case each of anaphylactoid reaction with mild
shock and angioneurotic edema with respirator
difficulty, both reversed with appropriate therap
In cases of allergic or hypersensitivity reactions
carisoprodol should be discontinued and appropri
ate therapy initiated. Suicidal attempts may pro
duce coma and/or mild shock and respirator
depression.

Dosage: Usual adult dose is one 350 mg. table
three times daily and at bedtime.

Supplied: Two Strengths: 350 mg. white tablet
and 250 mg. orange, two-piece capsules.

Before prescribing, consult package circular.

**for the relief
of low back
sprains and strain**

President's Letter

Disraeli once remarked that the thing he most wanted to see in any House of Commons member was that he be there. While the Minnesota State Medical Association has always had an excellent attendance at the Annual Meeting, which is continuing contrary to the experience of many state associations, some erosion has been occurring. This is a matter of concern to and constant scrutiny by both the Committee on Scientific Assembly and the Committee on Permanent Evaluation. The basic function of the Committee on Scientific Assembly is the development of a balanced program, the selection and acceptance of qualified speakers, and the arrangement of Round Tables, frequently utilizing speakers featured at the Clinical Sessions. The Committee on Permanent Evaluation, on the other hand, examines the Annual Meeting in all aspects: duration, time of the week and of the month, the banquet and other details, as only one of the many activities of the Association which it considers.

Some of the attrition obvious in all State Association Meetings is the rapid proliferation of specialty group meetings, post graduate courses, and increased hospital and clinic group programs, all intent on providing continuing physician education and equally intent on their own scheduling. The participation of drug firms in the programing, the honorarium for speakers, and the physical arrangements for many of these sessions have brought a new element and a professional touch into previously physician-arranged meetings. As yet no concern over a third party has arisen in this area of medicine in spite of the obvious comparison with other subsidies.

As medicine is reluctantly forced into a new era of patient-physician economics based on services indemnified, not as in the past, by patient-provided hospital-medical-surgical coverage on either a service or an indemnity basis, but rather by governmental decree, medical meetings may assume an entirely new format. Consideration may be given to a separation of the House of Delegates sessions from the clinical program, except in those larger organizations where delegate attendance is a far smaller proportion of the total. The time now necessarily devoted to the constantly expanding rules and regulations under which physicians of the future will practice requires from delegates and officers of all associations an increasing proportion of the actual meeting time, with a consequent decrease in attendance at the Clinical Sessions.

Since no decrease in the socioeconomic demands on physicians is forseeable in the future, some change is inevitable. What changes will occur are not predictable, but both continuing education and continuing physician awareness of these demands are essential. If, in consequence, separation of these two areas of physician participation to avoid overlap is necessary, future sessions could be arranged at different times to give equal emphasis to equally significant demands.

Total physician participation in meetings is never possible, for someone must tend the store; but maximum attendance is a goal.

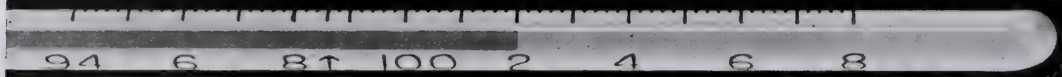
good reason
to select
Ilosone®
Erythromycin Estolate
for bacterial
infections



two to four times
the therapeutic
activity of other
erythromycins

CONTRAINDICATIONS: Ilosone is contraindicated in patients with a known history of sensitivity to this drug and in those with preexisting liver disease or dysfunction.

SIDE-EFFECTS: Even though Ilosone is the most active oral form of erythromycin, the incidence of side-effects is low. Infrequent cases of drug idiosyncrasy, manifested by a form of intrahepatic cholestatic jaundice, have been reported. There have been no known fatal or definite residual effects. Gastro-intestinal disturbances not associated with hepatic effects are observed in a small proportion of patients as a result of a local stimulating action of Ilosone on the alimentary tract. Although allergic manifestations are uncommon with the use of erythromycin, there have been occasional reports of urticaria, skin eruptions, and, on rare occasions, anaphylaxis.

DOSAGE: *Children under 25 pounds*—5 mg. per pound of body weight every six hours. *Children 25 to 50 pounds*—125 mg. every six hours. *Adults and children over 50 pounds*—250 mg. every six hours. For severe infections, these dosages may be doubled.

Available in Pulvules®, suspension, drops, and chewable tablets. Ilosone Chewable tablets should be chewed or crushed and swallowed with water.

Additional information available to physicians upon request.

Echovirus Type 18 Infection

An Unusual Exanthem

PHILLIPS P. WEDEMEYER, M.D.*
MARION K. COONEY, Ph.D.**
JOSEPH W. ST. GEME, JR., M.D.†
Minneapolis, Minnesota

In recent years it has been reported that many of the newly discovered enteroviruses, the Echovirus and Coxsackie virus, may be associated with an exanthem. The usual appearance of these exanthems has been macular or maculopapular, but they may be vesicular, papular, urticarial, or even petechial. Our present knowledge of the clinical features of these viral exanthems has been well summarized by Lerner, Klein, Cherry, and Finland.[1]

In 1959 Medearis and Kramer[2] described a child with a generalized maculopapular rash and Echovirus type 18 viremia. The present report details another instance of exanthem associated with Echovirus type 18 infection. Our patient differs from the original case in that the rash was more prolonged and simulated both erythema multiforme and erythema infectiosum.‡

Case Report

This one-year-old white girl was seen in our clinic on July 9, 1962, because of a rash of two weeks' duration and ataxia of one day's duration.

Two weeks previously she developed a fever of 102° F, and a fine discrete rash appeared on her face and the back of her neck. Mild rhinorrhea occurred after the onset of rash, but conjunctivitis, enanthem, and spread of the exanthem were not discerned by her parents.

Three days prior to her visit fever (102°F) recurred and the rash disseminated with marked involvement of the forehead, nose and back. The child developed anorexia and her stools became scant, thin, watery and foul smelling. Her postauricular lymph nodes were noted to be swollen.

On the day of the initial clinic visit the rash had faded from the forehead and face but had spread

‡See Test Your Word Score Page 1107.

to the distal arms and legs. The fever and adenopathy were said to have diminished. However, the parents observed that the child was irritable, lethargic, and tended to fall when walking.

Past History

The child had experienced no previous exanthems, cutaneous diseases, or allergic illness. There had been no exposure to drugs or to intense sunlight; nor had there been any recent change in soaps or diet.

Family History

There was no parental history of allergy or recent illness. The household consisted of the patient and her parents, and no known extrafamilial exposure to illness had occurred.

Physical Examination

The child was alert but apprehensive and irritable. Her rectal temperature was 100°F. There was no conjunctivitis or coryza. The pharynx was slightly inflamed. Slight enlargement of the postauricular, cervical, axillary, and inguinal lymph nodes was noted. The liver edge was palpable 3 cm. below the right costal margin and the spleen tip 1 cm. below the left costal margin. Meningismus and other neurologic abnormalities were not detected. Station and gait appeared to be normal.

A discrete, red, maculopapular eruption was observed on the forearms, distal upper arms, and the anterior surface of the trunk and legs. On the right leg hive-like lesions described a circular appearance, closely resembling the iris lesions of erythema multiforme.

The hemoglobin was 11.5 gm.% and the leukocyte count was 8,500/mm^3 with 35% neutrophiles, 56% lymphocytes, 6% monocytes, 1 eosinophile, 1 basophile and 1 plasma cell. A nasopharyngeal culture revealed many pneumococci, and a pharyngeal culture yielded no pathogens. A heterophile antibody determination and toxoplasma dye test were negative.

Clinical Course

The child was seen the next day and the rash was unchanged. She was treated with cool baths only. When seen one week later her rash was fading. At this time it was learned that a male cousin had developed a similar exanthem. Unfortunately, the cousin was not available for study.

Following this visit the family moved and the patient was lost to follow-up until contact was re-established one year later. The patient was healthy and developing normally. The exanthem had not recurred during the elapsed year.

Virologic Studies

The virologic studies were performed according to standard enterovirus methods.[3] A fecal specimen obtained on the 15th day of illness yielded a cytopathic virus in tube cultures of rhesus monkey renal cells. Neutralization tests employing type specific hyperimmune serum identified the virus as Echovirus type 18.

Neutralizing antibody assay was performed with paired acute (15th day of illness) and late convalescent (12 months) sera, using the patient's fecal isolate as the challenge virus. These studies revealed antibody titers of 1:4 and 1:16 respectively.

Discussion

The recovery of the Echovirus type 18 from the stool indicates only that enteric infection or infestation was present. However, this was the only Echovirus type 18 isolation made in Minnesota during 1962. Therefore, the pathogenetic implication of this virus isolation seems more plausible. The fourfold antibody rise supports the acute nature of the infection.

Regarding a differential diagnosis of this child's illness, the following clinical points should be considered. The duration of the rash was too long for any of the usual childhood exanthems except erythema infectiosum.[4] As with erythema infectiosum, the rash began on the face and later spread to the extremities. Although the morphologic nature of the exanthem simulated erythema infectiosum the usual lacelike component was absent, as was plasma eosinophilia.

The illness described by Medearis and Kramer[2] resembled that of our patient in many respects. The exanthem which appeared while the patients were febrile was erythematous, maculopapular, and blanched under pressure. The rash was blotchy, tended to be more discrete than coalescent, and faded without desquamation. There was no enanthem, conjunctivitis, or petechial eruption. Minimal adenopathy was detected. Both cases had loose stools but neither developed serious diarrhea.

The distribution of the rash in our patient tended to be peripheral, whereas for the child reported by Medearis and Kramer the distribution was generalized. The duration of the exanthem in our case was much longer and compatible not only with erythema infectiosum but also with erythema multiforme.

The child described herein re-emphasizes the great variety of exanthemata which may occur with enterovirus infection. Full appreciation of the complete spectrum of illness subsequent to infection with newly recognized viruses must depend in great part upon careful clinical observation and virologic study of abundant patient material. Most of these cases are seen by the practicing clinician who, with the collaboration of community laboratory facilities, has an unexcelled opportunity for productive clinical research.

Summary

The second case report of an exanthem associated with Echovirus type 18 infection is presented. The prolonged, benign exanthematous illness resembled erythema infectiosum, clinically, and erythema multiforme, morphologically.

Acknowledgment

We wish to thank Dr. D. N. Medearis, Jr., of the Department of Pediatrics, The University of Pittsburgh Medical School for kindly reviewing the manuscript.

WHAT'S YOUR DIAGNOSIS?

This 71-year-old white male walked into the emergency room of the Hospital about 10 P.M. one Friday night because of a 102 degree fever and a "smothering" feeling. He had been seen at home two weeks earlier with a flu-type syndrome but had gradually felt better until the morning of admission. Two years earlier he had had a 90% gastrectomy to control a massive (33 units of blood) bleeding from a gastritis. He had had emphysema for years and had nearly died several times postoperatively: once from a respiratory acidosis and once from a myocardial infarction and heart failure. He had been maintained on digitalis following the surgery but had had no other problems except failure to gain weight.

Physical examination was completely negative. Chest x-ray was normal except for the emphysema. WBC was 13,600 with 80% PMNs. Sputum, and throat cultures grew out normal flora. He was given a broad-spectrum antibiotic on an empiric basis. He felt more comfortable with an oxygen mask but still had a feeling of impending doom. Sixteen hours after admission he was incontinent of urine and stool; a Foley catheter was placed and from that point on until his death 70 hours after admission he passed less than 200 cc. of urine.

Twenty-four hours after admission a few soft rales were heard in each base; his digitalis was increased to 0.15 mgm. daily, and he was given 2 cc. of Salyrgan. This relieved his "smothering" feeling and he needed no more oxygen. Two EKGs were unchanged from the previous admission, and the ancillary lab tests also showed no sign of a recent infarction. Electrolytes obtained after the onset of oliguria were a CO_2 combining power of 26, chloride of 89, and potassium of 6.4 mEq/L.

Forty-eight hours after admission his previously normal blood pressure dropped to zero and he became comatose; his temperature dropped to normal and WBC to 7,400. He was treated with 100 mgm. of Solucortef every four hours and 1 cc. of Aramine every hour, but we could not maintain a systolic pressure of over 90. Levophed by IV drip did maintain an adequate pressure, and dibenzaline 10 mgm. b.i.d. was also given in hopes this would aid the urinary output; but he died 15 hours later without regaining consciousness.

What is your diagnosis? Turn to page 1071.

Humaniculture

In 1906 appeared a book titled Humaniculture by one Hubert Higgins, a man well qualified to write a treatise on health because of the professional posts he held as Demonstrator of Anatomy at the University of Cambridge and Assistant Surgeon to Addenbrooke Hospital, Cambridge, England. The book is unique mainly for its endorsement of Fletcherism, then regarded as a new coefficient in the health equation.

The author maintained that though Fletcherism was an 'ism', it had scientific sanction, as he proceeded to demonstrate by his use of the words poltophagy* and psomophagy,* two contrasting methods of ingesting food. He pointed out that the chewing and swallowing mechanisms of the herbivorous horse and the carnivorous dog show a sharp physiological difference, the horse being obliged to masticate and insalivate his food thoroughly before swallowing; but not so the dog, who tears off morsels and swallows them with almost no chewing. Hence the horse is a poltophagist and the dog a psomophagist.

Man, however, is neither poltophagic nor psomophagic exclusively. Structurally and metabolically he falls somewhere between, favoring the horse, however, more than the dog, which means that for optimum nutrition it is incumbent on him to chew his food longer and better than he habitually does.

Furthermore, Higgins contended that thorough mastication reduces the amount of food man needs; and consuming less, he will be healthier, feel more energetic, and function more efficiently.

While Higgins did not advocate counting mastications, he pointed out that Mr. Gladstone attributed his phenomenal strength and endurance to the practice of poltophagy to the tune of thirty to thirty-five chews for each mouthful of food (an estimate later amended, however, by an interested observer who counted sixty to seventy jaw movements on the part of the prime minister).

Nor did Higgins recommend hyper-mastication, which would invest the process of chewing and swallowing with such prolonged and tedious attention as to detract needlessly from the gustatory pleasure of eating.

While Humaniculture (1906) may be gathering dust on library shelves and Fletcherism may be obsolete, poltophagy remains a good word for a practice which might more profitably be engaged in by the all too numerous affluent and corpulent Americans these sixty years later.

On Coral

Thirteenth century Vincent of Beauvais, in his enthusiasm over the therapeutic virtues of coral, claimed that it checked hemorrhage, reduced corpulence, drew harmful humors from the eye, cured ulcers, and benefited heart, intestines, and spleen. Suspended over the mouth it stopped stomach-ache; suspended from the neck it prevented epileptic fits.

The fundamental rule of progress is to do what you can with what you have, where you are today. — R & R Magazine

Primary Hyperpara—Thyroidism

The Importance of Early Diagnosis

LAURENCE E. WINTER, M.D.*
DONALD G. MC QUARRIE, M.D.*
Minneapolis, Minnesota

PRIMARY HYPERPARATHYROIDISM is an uncommon, though not a rare disease. Since Mandl[1] removed the first parathyroid adenoma in 1926, hyperfunctioning parathyroid tissue has been sought with diligence by surgeons throughout the world. There are now several series[2-4] of over 100 cases, and general awareness of the disease's clinical features has increased. The correct diagnosis, however, is all too often not entertained until the disease becomes advanced. The early symptoms of primary hyperparathyroidism: polyuria, polydipsia, anorexia, fatigue, weakness, headache, constipation, and mental imbalance are so protean** as to rarely lead to a diagnosis. However, examination of the case presented below would suggest that more careful attention paid to the early symptoms can result in an earlier diagnosis and the avoidance of serious late complications.

It is the purpose of this paper to present the recent experience of this hospital with cases of primary hyperparathyroidism which came to surgery, and to emphasize clinical features of the disease which can facilitate an earlier diagnosis.

Material

The present series is composed of 24 patients between the ages of 23 and 75, with a mean age of 51.5 years. Most large series are composed of approximately three women to one man. But since the population of this hospital is almost exclusively male, no cases were encountered in women.

The study covers the period 1948 to 1964, during which time there were 164,142 admissions. The 24 cases represent an incidence of approximately one in 7,000 admissions.

Clinical Features

Each patient presented with a complex of symptoms involving multiple systems (Table 1). A renal calculus was the most frequent complication and was encountered in all but three patients. Three of the patients with musculoskeletal pain as a chief complaint had x-ray evidence of bone cyst formation. In all, 11 patients showed x-ray indication of decreased lamina dura of the teeth and/or bone cyst formation. The diagnosis of peptic ulceration was arrived at by laparotomy or x-ray demonstration. Six of the seven ulcers occurred in the duodenum and were all particularly refractory to conservative treatment. An incidental finding involved a patient being treated for a recent stroke with a history of renal stones in the past.

Table 2 summarizes the prominent clinical features which accompanied the chief complaints and which predated diagnosis by an average of seven years in this series. In addition to the expected high frequency of urinary and musculoskeletal system involvement, attention is called to the relatively high frequency of the less commonly appreciated symptoms such as anorexia, headache, polyuria, constipation.

TABLE 1
Incidence of Chief Complaints

Symptom	Incidence
Renal stone	11 (48.3)
Musculoskeletal	7 (29.2)
Ulcer	3 (12.5)
Mental illness	2 (8.3)
Incidental	1 (4.2)

TABLE 2
Incidence of Symptoms Accompanying the Chief Complaint

Symptom	Incidence
Renal Stone	21 (87.5)
Constipation	16 (66.7)
Headache	14 (58.3)
Musculoskeletal	13 (54.5)
Anorexia	13 (54.5)
Polyuria and polydipsia	11 (48.3)
Hypertension	9 (35.5)
Fatigue and weakness	8 (33.3)
Mental illness	6 (25.0)

TABLE 3
Incidence of Pathology

Tissue	Incidence
Single adenoma	19 (79.2)
Double adenoma	1 (4.2)
Carcinoma	0 (0.)
Primary hyperplasia	4 (16.7)

Laboratory Diagnosis

A number of rather elaborate tests and measurements have been devised in an attempt to distinguish the hyperfunctioning parathyroid state from other similar conditions.[5-10] At present, there is no clinically available method of assaying parathormone blood levels in man; thus the level of gland activity must be inferred from the effects of the hormone on calcium and phosphate metabolism.

Serum Calcium

The most useful screening test in this series was the serum calcium level. Determinations on patients in this series ranged from 9.2 to 20.2 mgm/100 cc. Each patient, however, had at least one value over 11.1, and 20 of the 24 patients had at least one value over 11.6.

Serum Phosphate

The serum phosphate level was frequently raised by the renal damage commonly observed with hyperparathyroidism, thus masking the classic hypophosphatemia. In nine cases the serum phosphate level was consistently below the lower limits of normal; but in two others it was above the upper limits of normal on at least one determination.

Urine calcium levels reflected the serum levels and were abnormally high on at least one determination in each case. At this institution, serial serum calcium determinations have given the most reliable screening and confirmatory assistance. The alkaline phosphatase was abnormally high in six cases, and 12 patients had elevated blood urea nitrogen. The tubular reabsorption of phosphate test was performed in 12 cases and was low in seven.

Pathology

Table 3 summarizes the histologic changes in the glands. Twenty (83.3%) of the 24 cases were due to adenomas. Of the 21 adenomas recovered, 16 were formed predominantly of chief cells, and five of water-clear cells. The lower pair of glands was involved in 76% of the cases. In only one instance was it necessary to perform mediastinal exploration to recover the adenoma. Primary hyperplasia was encountered in four cases, all of which were made up predominantly of clear cells. There were no cases of parathyroid carcinoma. One case was suggestive of the multiple endocrine adenomata syndrome in that the patient had had a symptomatic islet cell adenoma of the pancreas removed 14 years prior to removal of a chief cell adenoma.

Case Report

A 35-year-old colored waiter was first worked up at this hospital for complaints of nausea, constipation, abdominal pains of a vague nature, and dull leg pains. Physical examination and an upper G.I. series were unremarkable. The patient was discharged with a diagnosis of lumbosacral myofasciitis. He returned two years later with the same above complaints and a persistent frontal headache. This time he was discharged without specific treatment, only to return the following year with the same problems. He was then felt to have an organic neurologic disease, type undetermined, and received antiluetic therapy. A salivary calculus was noted on that admission. The patient returned to work but had gradual progression of musculoskeletal pain which became generalized.

Sixteen years after originally seen, the patient noted the onset of polyuria and polydipsia to such a degree that his work was interfered with. Bone pain, weakness, and fatigue became so severe that he became essentially an invalid.

The patient returned for his fourth admission 21 years after first seen. He was noted to be a thin, feeble, colored man appearing 20 years older than his stated age. Blood pressure was 165/105. There was marked weakness of all muscle groups. A one-cm. mass was palpated in the left lobe of the thyroid gland. Serum calcium was 17.5, serum phosphorus 4.5, alkaline phosphatase 72, BUN 40; and 24-hour urine collections for calcium were 512 and 300 mgm. on a Bauer-Aub diet. An IVP revealed a calcification of the lower pole of the left kidney and nephrocalcinosis. X-rays of the long bones revealed polycystic changes. The patient was taken to surgery where a chief cell adenoma was removed.

Over the next two months, the patient's bone films improved markedly, and his bone and abdominal pains resolved. He became mentally clear and ambulatory for the first time in several years. Two years later, however, he returned with continued complaints of headache, a blood pressure of 190/126, and early congestive failure. He became well enough to leave the hospital, but returned the next year confused, dehydrated, febrile, with a blood pressure of 178/110, a BUN of 125, and a serum phosphorus of 10. He deteriorated rapidly and died on the third hospital day. Post-mortem examination revealed far advanced renal disease.

Discussion

Complaints referable to the urinary and musculoskeletal systems are the most common antecedents to the diagnosis of hyperparathyroidism.[11,12] The striking feature of Table 2, however, is the high incidence of less commonly appreciated symptoms. The appearance of these symptoms usually predated the diagnosis by several years, but their significance was not properly appreciated by either the patient or the physician. It should be emphasized that the nonspecific symptoms, as in the above case, were usually a prominent part of the history, and were on occasion so severe that the patient was incapacitated. It would seem that if earlier diagnosis is to be made, more attention must be given to the less specific symptoms. Any one or two of these symptoms alone are too protean to suggest hyperparathyroidism; however, a combination of these complaints should arouse the suspicion of hyperparathyroidism and warrant a serum calcium determination.

Summary

Twenty-four cases of primary hyperparathyroidism are presented in which the diagnosis was confirmed by surgery. Arrival at an earlier diagnosis through a higher index of suspicion when presented with the early symptoms of the disease is emphasized.

We wish to express our thanks to E. W. Humphrey, M.D. for his help in preparing this paper.

IT'S THE LAW
Recent Court Decisions Tend to Favor Patients*

A New York housewife was burned by x-ray treatment for bursitis. Years later another doctor warned her that the scars could develop cancer. She sued the radiologist and collected $25,000. Ten thousand was awarded for the burns and $15,000 for the cancerophobia she developed. The New York court of appeals ruled that the wrongdoer is liable for the ultimate result.

Extending malpractice damages to cover mental disturbances is only one of a number of new legal doctrines; some lawyers maintain that the rules have too long favored the doctors. Attorney Lou Ashe, a San Francisco lawyer and partner of the much publicized Melvin Belli, states: "Some judicial inroads are being made on previous inflexible rules of proof" which have protected doctors. Doctors and defense lawyers are coming perilously close to the principle that doctors would be financially liable for unsuccessful treatment whether they are negligent or not.

A New Yorker recently brought a successful suit against a medical laboratory for mental anguish caused by an inaccurate report that he was sterile. The state court of appeals observed: "Freedom from mental disturbance is now a protected interest in this state."

Of more widespread import are new rules breaching heretofore important defense procedures. Previously, a patient had to produce a doctor to prove his claim. A California judge complained that a plaintiff in a malpractice suit could get testimony only from an occasional "lone wolf" willing to risk ostracism by his fellow practitioners and cancellation of his insurance policy. Some courts are now permitting exceptions to the rule requiring medical testimony. One such exception is on the principle of "res ipsa loquitur," meaning "the thing speaks for itself." Judges are ruling that expert medical testimony is not necessary when the patient suffers obvious injuries; the injury speaks for itself and the defendant must accept the burden of defense. A landmark case occurred in San Francisco where a housewife suffered a facial paralysis following a mastoid operation. During the trial no medical evidence was introduced to the effect that the surgeon was negligent. The defense testimony showed that the injury though rare did occur unavoidably in a small percentage of mastoid operations. The judge, on the basis that the injury to the nerve was obvious, put the question to the jury, which awarded $40,000 to the patient. This decision was upheld by the California court of appeals.

It is quite evident that because of the very large awards given against doctors, the old $25 yearly premium for $10,000 to $25,000 policies is outdated.

MERLE BAH, M.D.**
ALVIN W. WATERS, M.D.†
St. Paul, Minnesota

NONE OF OUR concepts solves the riddle of sarcoidosis today, as the etiology and pathogenesis still remain obscure. It seems that sarcoidosis with its many strange features belongs to a borderland with similarities to established infections and still etiologically obscure conditions as collagenoses, Hodgkin's disease and real tumor disease."[1]

Case Report

A 79-year-old negro female was admitted for the first time in September, 1960, with a history of nausea, vomiting, weakness and a 16-pound weight loss of several months' duration. Generalized pruritus was present since the late 1950s without evident skin lesions. No history of bleeding, dyspnea, cyanosis or wheezing was obtained. Peripheral edema was questionably present in the mid-1950s. She had been taking digitalis irregularly since then.

Physical Findings

The physical examination revealed an elderly, well-developed, well-nourished negro female in no acute distress. The pertinent positive findings included very dry skin, swelling of the distal interphalangeal joints, grade III/VI systolic murmur with maximum intensity at the base of the heart, and liver palpable 3 cm. below the costal margin at the right midclavicular line. The lungs were clear. No tumor masses, splenomegaly or lymphadenopathy were palpated. No skin lesions were observed. Neurological examination was within normal limits.

Laboratory Studies

The hemoglobin was 8.7 gm.%, red blood cell count was 3.1 million, reticulocyte count 2.8%, and white blood cell count 8600 with a normal differential.

Urinalysis showed specific gravity of 1.010 on several occasions but was otherwise negative.

The erythrocyte sedimentation rate was 92 mm. in one hour. Serum electrophoresis revealed a slight increase of gammaglobulin, but the total serum protein was normal. Serum calcium was 11.5 mg.%, serum phosphorus 7.0 mg.%, alkaline phosphatase 9.6 units (King-Armstrong), blood urea nitrogen 58 mg.% and serum creatinine 4.3 mg.%. Sodium,

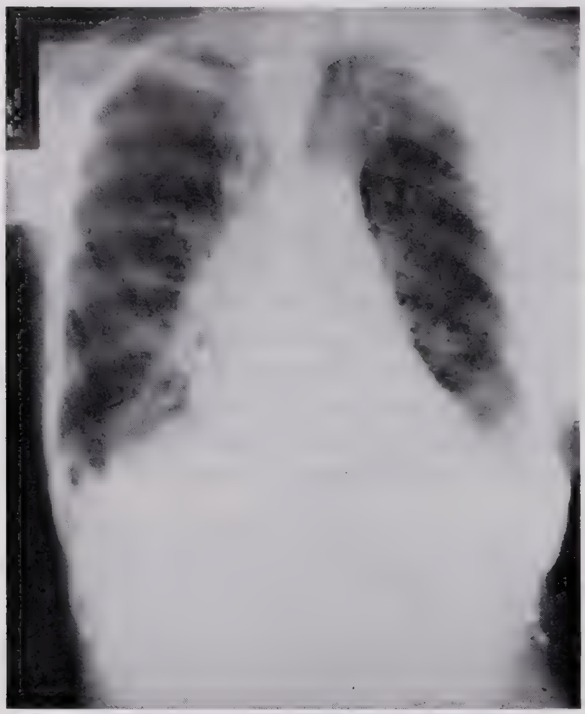

Fig. 1 — Slight emphysema and basilar fibrosis are seen. To the left the partly calcified axillary tumor is just visible. In the left supraclavicular region another calcified mass is observed.

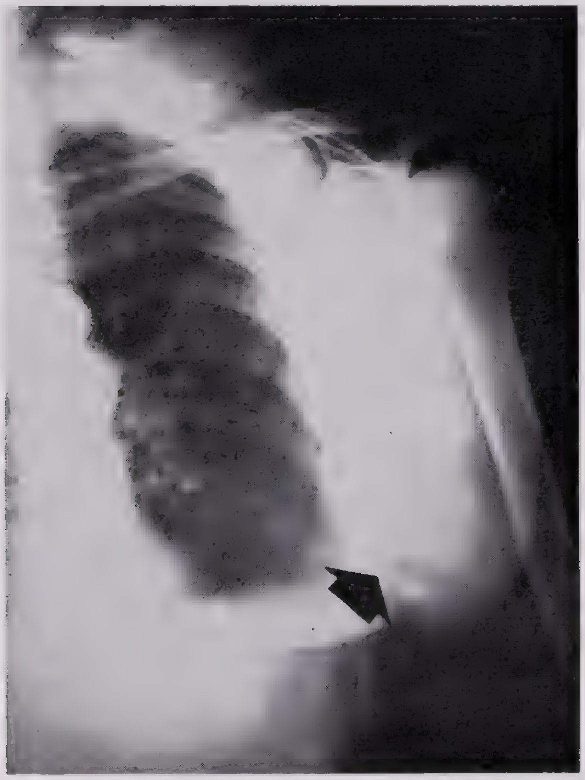

Fig. 2 — The left axillary mass is here seen. Note the layering of calcium in the dependent portions of the tumor.

potassium, chloride and bicarbonate in serum were within normal limits.

The bone marrow aspirate showed an anemic pattern but was otherwise not diagnostic.

Upper gastrointestinal and colon x-rays were essentially negative. Chest x-ray showed mild pulmonary emphysema and basilar fibrosis.

Progress

After the above work-up, the patient received oral iron and blood transfusions and was discharged with the diagnosis of nonspecific anemia. The digitalis was discontinued upon admission.

She was followed in the outpatient department at regular intervals. Her anemia persisted and she complained of progressively increasing pruritus, which a dermatologic consultant was unable to explain.

Second Admission

The patient was again admitted in May, 1961, with history of a tumor mass above her left iliac crest first noticed one month previously. The mass was nontender, firm, smooth, attached to the skin and to the underlying structures, and measuring 5 cm. in diameter. The physical examination also revealed a similar mass of about the same size in the left axilla. Roentgenologic studies showed both the masses to be calcified.

The iliac tumor mass was biopsied and showed a cyst-like formation with foreign bodies like granulomas. The patient refused biopsy of the axillary mass.

Third Admission

The patient was readmitted in August, 1962, because of pain in the left axillary mass. The physical examination now showed a mass of 2 cm. in diameter in the left supraclavicular region, a mass of 2-3 cm. in diameter on the left thigh, in addition to the other lesions, earlier described, which had not changed in size.

The axillary mass was aspirated and 75 cc. of salmon-colored fluid was obtained. Cultures were negative for bacteria, including acid-fast bacilli, as well as for fungi.

Upright films of the left axilla and supraclavicular areas showed loculation of the masses which contained calcium-like densities which layered out in the dependent portions of the masses.

A bone survey x-ray was essentially negative.

A venogram of the left arm showed no venous connection with the tumor.

The hemoglobin was 10.6 gm.%. White blood cell counts were within normal limits. Cell differential counts now showed an elevation of eosinophils to 11, 6 and 5 % on three examinations.

Urinalysis showed + for albumin on several occasions.

Serum calcium was 12.3 mg.%, serum phosphorus 6.9 mg.%, and alkaline phosphatase 4 and 6.9 units (King-Armstrong). Twenty-four hour urinary calcium excretion was repeatedly within normal limits. The erythrocyte sedimentation rate was 50 mm. in one hour. The protein-bound iodine was 6.6 microgm.%. Bromsulphthalein was 1.2% retention at 45 minutes. The electrocardiogram was within normal limits except for an incomplete right bundle branch block.

Final Admission

Except for increasing weakness the patient noted no particular change in her symptoms until spring, 1963, when the tumors in the left axillary and supraclavicular regions appeared to increase rather rapidly in size. The patient was admitted to Bethesda Lutheran Hospital, St. Paul, in July, 1963.

The left supraclavicular mass now measured 10 cm. in greatest diameter and the axillary mass was slightly larger.

Flat and upright x-rays of the supraclavicular and axillary regions showed loculated fluid containing masses with calcium-like densities (Figures 1 and 2).

The left knee showed a soft tissue calcification similar to that in the axilla (Figure 3).

A film of the abdomen revealed normal-sized kidneys with no renal calculi demonstrated.

The described tumor near the left knee was biopsied. The microscopic examination showed "dense fibrous tissue with relatively acellular structure. The inner surface of the cystic lesion was covered by an irregular layer of granular material identified as calcium. There were a few foreign body giant cells present."

No essential change was recorded this time. The blood urea nitrogen, however, had increased to 76 mg.%. The serum calcium was between 11.0 and 12.5 mg.% on several occasions. The twenty-four hour calcium excretion in the urine was constantly within normal limits. The serum protein was 5.6 gm.% with an albumin/globulin ratio of 1/1.07.

Hospital Course

The patient had a few episodes of paroxysmal atrial fibrillation during this hospitalization. She converted to sinus rhythm with digitalis and was maintained at normal sinus rhythm on low maintenance dosage. She had on one occasion a transient elevation of the blood pressure from normal level to systolic greater than 300 mm. Hg, but she was successfully treated with reserpin.

During the hospitalization the patient's condition was characterized by increasing

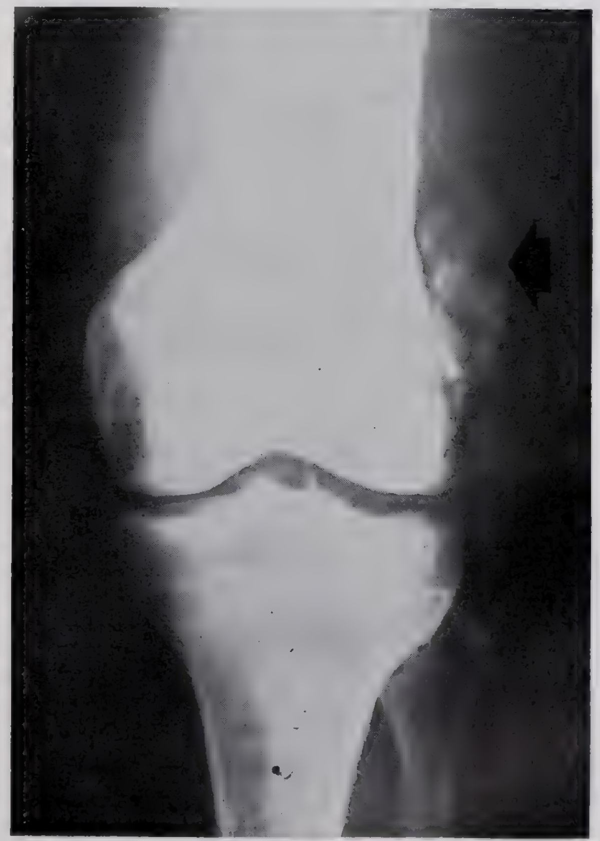

Fig. 3 — Calcification in the soft tissue adjacent to the left knee.

weakness and episodes of unconsciousness and confusion. She gradually deteriorated and suddenly expired.

Necropsy Findings

The post-mortem examination showed that the axillary and supraclavicular masses were multiloculated cystic tumors filled with salmon-colored fluid with a slight granularity. The cyst wall was 6-10 mm. thick and fibrinous in consistency. Numerous mediastinal lymph nodes up to 2 cm. in diameter were found, with a particularly prominent group of nodes at the root of the great vessels. The lymph nodes were on the superior and anterior surfaces of the left subclavicular vein and encompassed the thoracic duct. This region was very densely scarred. In the left thoracic cavity there was approximately 2000 cc. of milky fluid. The liver was slightly enlarged, weighing 1850 gm. The spleen appeared tannish-brown and had an increased fibrous consistency.

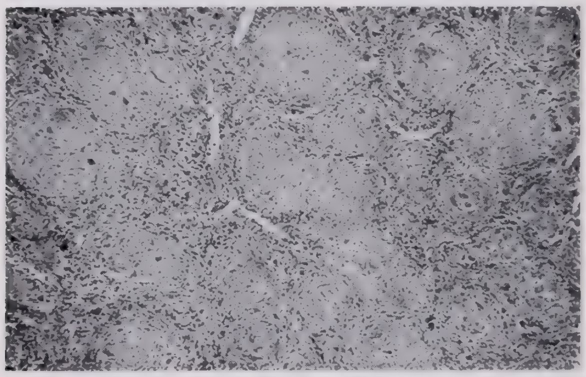

Fig. 4 — Section of spleen. Noncaseous granulomas are scattered all over the picture. (40 x)

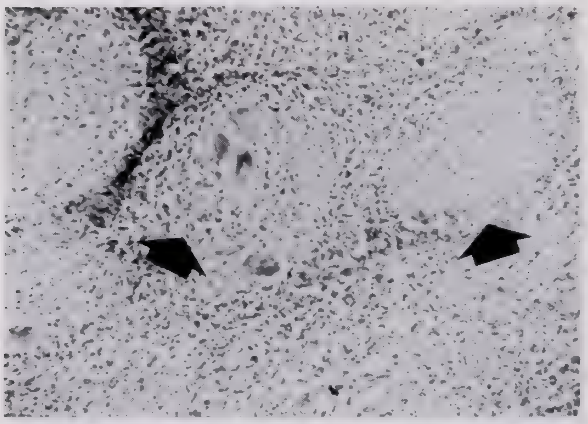

Fig. 5 — Spleen. Higher magnification of granulomas. (100 x)

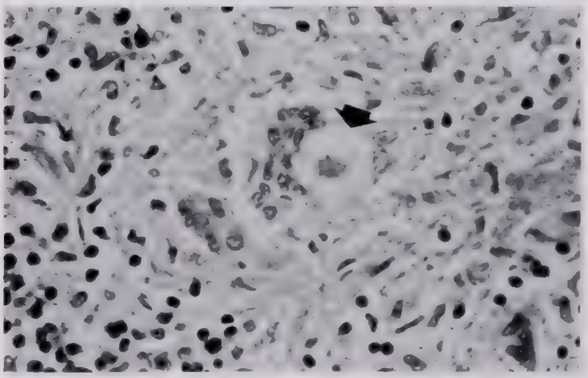

Fig. 6 — Multinucleated giant cell with an "asteroid" inclusion body can be seen in the centre of the picture.

The necropsy conclusions were as follows:

1. Sarcoidosis involving anterior superior mediastinal and thoracic lymph nodes, obstructing the thoracic duct and involving the liver and spleen (Figures 4 and 5). The axillary cyst wall showed giant cells and many areas of calcification (Figure 6).
2. Arterionephrosclerosis and macroscopic tubular calcification.
3. Left chylothorax — secondary to obstruction of the thoracic duct.
4. Old degenerated thyroid adenoma.
5. Pulmonary emphysema.
6. No malignancy was found. The parathyroid glands were identified and normal.

Clinical and Pathological Discussion

The patient had a persistent, marked elevation of her serum calcium. Evaluation of the etiology of this abnormal finding led us to the following differential diagnoses:

1. Primary hyperparathyroidism. 2. Malignant disease with or without metastases to the bones.[2-6] 3. Sarcoidosis. 4. Hyperthyroidism. 5. Paget's disease. 6. Milk-alkali syndrome. 7. Immobilization. 8. Vitamin D intoxication.

Vitamin D intoxication, immobilization, and milk-alkali syndrome can be promptly excluded in view of the lack of history. Laboratory findings and x-ray studies also eliminate Paget's disease.

Hyperparathyroidism

This diagnosis was not excluded pre mortem. X-ray studies and some laboratory results, however, did not support the diagnosis.

Bone survey x-ray did not show any osteoporosis, osteosclerosis, or punched-out areas in the distal phalanges.

The urinary excretion of calcium was always normal and not elevated as might have been expected. A normal excretion of calcium frequently occurs in advanced hyperparathyroidism with impaired renal function.

The serum phosphorus was elevated and not decreased, as is often seen in this disease. An elevated serum phosphorus, however, can be found when the kidney function is impaired and often in elderly patients or in sarcoidosis.[7] The alkaline phosphatase was normal, which is the rule in hyperparathyroidism without bone lesions. It should be emphasized that hypercalcemia may be the only abnormal laboratory finding in hyperparathyroidism.[8,9]

Consequently this disease was not ruled out pre mortem. No steroid administration test was performed.[10] The autopsy findings, however, showed normal parathyroid glands.

Malignancy

The patient's age favored a malignancy. Severe pruritus is occasionally accompanied by a malignant disease. Malignancies of the breast, lung, kidney, ovary, prostate and pancreas as well as malignant lymphoma, multiple myeloma and leukemias with or without bone metastases can produce hypercalcemia.[2-6]

Furthermore, extensive soft tissue calcifications have been reported in cases of carcinoma in the gastrointestinal tract.[11] Finally, the clinical course in this case is also consistent with a malignant disease. The biopsies as well as the autopsy were negative for malignancies.

Hyperthyroidism

Hyperthyroidism rarely causes hypercalcemia. The patient did not manifest any clinical evidence of hyperthyroidism. She repeatedly had episodes of slow atrial fibrillation readily converted to sinus rhythm with digitalis, which would tend to rule out hyperthyroidism as a cause of the atrial fibrillation. Repeated normal values of protein-bound iodine and normal basal metabolic rate also opposed the diagnosis of hyperthyroidism. At autopsy the thyroid gland was normal except for an old degenerated adenoma.

Sarcoidosis

This patient presents with subcutaneous masses, hepatomegaly, hypercalcemia, hypergammaglobulinemia and azotemia. These are not infrequently reported findings in sarcoidosis—at least in this country.[12] Hypercalcemia has been reported in 20-30% of sarcoid patients in the United States and in 10% in a communication from England.[13-15] Sarcoidosis may involve any organ, but most frequently seen clinically are:[12] lung, 40-85%; mediastinal and/or hilar adenopathy, 57-100%; liver, 6.9-43%; spleen, 8.2-42%; peripheral lymph nodes, 37-100%; skin and subcutaneous tissue, 7.1-63%.

The biopsies were very suggestive of sarcoidosis. However, the normal chest x-ray without hilar lymphadenopathy combined with the unusual roentgenological appearance of the tumors produced a confusing picture.[16,17] Large calcifications are very rare in sarcoidosis[18] but are occasionally seen in tuberculosis. Calcifications in sarcoidosis are commonly small and eggshell-shaped in the lung or in a lymph node.

Furthermore, the formation of cavities in the soft tissue was puzzling. Cavities in lungs with sarcoidosis have been reported sporadically but are rare.[19] Some of these reported cavities have also contained fluid more or less hemorrhagic in character. In one case secondary fungal infection was reported in a sarcoidosis patient with a pulmonary cavity.[20,21]

The post-mortem examination revealed a left chylothorax secondary to obstruction of the thoracic duct by enlarged scarred granulomatous lymph nodes.[22] Thoracic duct obstruction has been seen in malignancies and tuberculosis, but to our knowledge it has not been previously described in a case of sarcoidosis. A similar obstructive phenomenon attributed to sarcoidosis has been reported as a cause of portal hypertension with esophageal varices.[23]

Sarcoidosis is now considered to be a

nonspecific entity characterized by the granulomatous appearance of tissues. Many agents have been implicated in the etiology of the reaction, such as bacteria, fungi, foreign bodies, chemicals and different tumors. Its immunological resemblance with Hodgkin's disease is noted.[24] It is likely that more specific etiological factors will be discovered, and accordingly fewer cases will occur in the broad category now called sarcoidosis.[25,26]

Summary

A case of sarcoidosis with some interesting necropsy findings is presented. An elderly negro female was admitted with a history of fatigue, vomiting and generalised pruritus. The positive findings in her work-up were hepatomegaly, hypercalcemia, anemia, azotemia and hypergammaglobulinemia. She also developed during a three-year period subcutaneous, partly calcified tumors, the biopsies of which showed a granulomatous tissue with foreign body giant cells. Pulmonary changes and hilar adenopathy were clinically absent. A downhill course similar to that seen in malignancies occurred.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 1059)

Classical bilateral severe necrotizing bronchopneumonia. It is possible in early pulmonary disease to have a normal x-ray finding. With continuing symptoms, a repeat of the chest films should be done, because pneumonia can always be identified on the x-ray film. Cultures were not taken, as the autopsy was done at the mortuary and the body had already been embalmed.

He also had a severe nephrosclerosis and severe coronary sclerosis with an old (two-year) myocardial infarction.

Acute Myeloid Leukemia

Treatment of with 6-Mercaptopurine and Cyclophosphamide*

B. J. KENNEDY, M.D.**
JOHN W. YARBRO, M.D.†
RICHARD S. KRONENBERG, M.D.‡
Minneapolis, Minnesota

THE CURRENT DRUG therapy for acute leukemia utilizes only a few specific chemotherapeutic agents as well as such nonspecific measures as antibiotics, transfusions, and adrenocortical steroids. By far the most successful of the chemotherapeutic agents has been 6-mercaptopurine. Its use since 1952 has significantly prolonged survival, particularly in children with acute lymphocytic leukemia.[1] Unfortunately this improvement in prognosis is much less evident in adults; current figures list the average survival in all types of acute leukemia as under five months.[2] These facts stimulate a continued search for a more effective therapy.

The prolonged use of 6-mercaptopurine in the control of acute myeloid leukemia frequently cannot be attained under circumstances in which the platelet count is below 50,000 cmm. The thrombocyte-depressing effect of 6-mercaptopurine accentuates the already existing thrombocytopenia. Therefore, in the presence of thrombocytopenia, short courses of 6-mercaptopurine were utilized for five to ten days at weekly intervals without the complication of further platelet depression. This attempt failed to produce any significant change in the leukemic process.

It was therefore considered that the use of this short-term course of 6-mercaptopurine might be aided by the concomitant use of some other cytotoxic compound. Since cyclophosphamide appeared to have a platelet sparing effect, single massive doses of intravenous cyclophosphamide were employed in combination with short courses of

‡Fellow in Internal Medicine.

6-mercaptopurine in ten adults with acute leukemia. Substantial changes occurred in the peripheral blood and bone marrow in the form of a decrease in white blood cells and blast cells and an increase in the platelet count and hemoglobin.

Although the data accumulated thus far is small, the consistency of the observations was worthy of presentation as a stimulus to further exploration of this mode of treatment.

Dosage Schedule

This combination chemotherapy regime consisted of 6-mercaptopurine in a dose of 2.5 mg. per kg. per day orally for five days, and on the sixth day cyclophosphamide was administered intravenously in a single dose of approximately 40 mg. per kg. Each course of therapy was repeated when the white blood cell count increased or blast cells reappeared. Prednisone was usually utilized concomitantly.

Results

The combination therapy of 6-mercaptopurine and cyclophosphamide was administered to ten patients with acute leukemia (Table 1). Two of the patients had chronic myeloid leukemia that was in an acute phase, three had subacute myeloid leukemia, and four had acute myeloid leukemia. One patient had an erythromegakaryocytic leukemia or a myeloproliferative syndrome.

In two patients (Cases 9 and 10) the cyclophosphamide was administered on the day of death or within a few days prior to death. One patient with subacute myeloid leukemia appeared to have an increase in the platelet count following the first course of combination therapy; but the development of a cerebral vascular episode on the basis of arteriosclerosis was a cause of discontinuance of leukemia therapy, and the patient died within two and one-half months of initiating treatment (Case 7).

Case Reports

Case 5

This 17-year-old boy had a two-month history of weakness. At the time of diagnosis, the white blood count was 26,300 with 41 per cent myeloblasts. The platelet count was 24,000 cmm. Bone marrow examination revealed 14 per cent myeloblasts, 2.6 per cent normoblasts, and decreased platelets. A diagnosis of subacute myeloid leukemia was established.

Because of the thrombocytopenia, two short courses of 6-mercaptopurine at 100 mg. a day for three days were administered with prednisone. The platelet count gradually decreased to 8,000 and the white blood count rose to 106,000. The hemoglobin decreased (Figure 1). Therefore, following four days of 6-mercaptopurine at 100 mg. a day, 2.75 gm. of cyclophosphamide was administered intravenously. There was a subsequent decrease in white blood count, a decrease in myeloblasts, an increase in hemoglobin, and an increase in platelets to normal ranges. At the end of five weeks, a repeat bone marrow examination revealed a hypoplastic marrow with a relative normoblastic hyperplasia. The normoblasts were 50 per cent and the myeloblasts 1.5 per cent; the platelets were normal. This remission lasted for three and one-half months.

At the time of the recurrence of the disease,

TABLE I
Data of Ten Patients Treated with 6-Mercaptopurine and Cyclophosphamide

				Duration (Months)					
Case No.	Sex	Age	Type of Myeloid Leukemia	Symptoms to Treatment	Treatment to Death	WBC Decreased	Myeloblasts Decreased	Hemoglobin Increased	Platelets Increased
1.	M	29	Acute	6.	2.	+	+	0	0
2.	F	52	Acute	1.	0.4	+	+	0	0
3.	M	70	Acute	0.3	2.3	+	+	0	0
4.	F	33	Acute	3.	9.	+	+	+	+
5.	M	17	Subacute	2.	10.	+	+	+	+
6.	F	67	Subacute	2.	1.	+	+	0	0
7.	F	63	Subacute	5.	2.5	+	—	0	?
8.	F	40	Chronic (acute phase)	69.	5.	+	+	+	+
9.	M	20	Chronic (acute phase)	8.	< .1	—	—	—	—
10.	F	70	Erythromegakaryocytic	24.	< .01	—	—	—	—

cyclophosphamide was administered without 6-mercaptopurine, followed by a decrease in the white blood count from 42,000 to 1,000 but no improvement in the platelet count. Two weeks later, a repeat course of 6-mercaptopurine and cyclophosphamide was administered with a decrease in the white blood count and improvement in the platelet count. This remission lasted two months. Subsequently the patient received repeated trials of therapy and expired ten months after the initial treatment. During this interval he received two courses with cyclophosphamide only, one course with 6-mercaptopurine only, one course with the combined therapy utilizing a low dose of cyclophosphamide, and two combination courses in which cyclophosphamide was administered in a dose of 2.75 gm. It was only with the latter combined regimen that an increase in the platelet count occurred.

Case 8

This 40-year-old woman was first known to have chronic myeloid leukemia in 1959. One year later, because of a white blood count of 40,000 and an iron deficiency anemia of 8.8 gm., ferrous sulfate was administered with an increase in the hemoglobin to normal ranges and a decrease in the white blood count to 12,000. This patient was followed for seven and one-half years from the onset of the disease. During the sixth year, an increase in the white blood count to 90,000 occurred and was followed by a spontaneous decrease to 40,000. Subsequently, because of the appearance of myeloblasts in the periphearal smear, 6-mercaptopurine was administered with a decrease in the total white blood count (Figure 2). Two and one-half months later, the disease reactivated and failed to respond to 6-mercaptopurine. Therefore 2 gm. of cyclophosphamide was administered with an abrupt drop in the white blood count and a disappearance of myeloblasts from the peripheral smear. This remission persisted for two and one-half months. Subsequently, the myeloblasts reappeared in the peripheral smear and disappeared following each course of combined 6-mercaptopurine and cyclophosphamide. Gradually, however, the platelet count decreased and death occurred from hemorrhage five months after the first course of combined 6-mercaptopurine and cyclophosphamide. The initial course of combined therapy produced a decrease in the total white blood count, a decrease in the blasts to zero, an increase in the hemoglobin, and an increase in the platelets.

Case 3

This 70-year-old man had acute myeloid leukemia. The white blood count was 250,000, of which 75 per cent were myeloblasts. The platelet count was reduced. The patient was acutely ill with thrombocytopenia and hemorrhage. Combination therapy produced an abrupt drop in the white blood count, myeloblasts, and platelets. Subsequently three other episodes of leukocytosis occurred with an increase in the myeloblasts. Combination therapy was followed by a decrease in the white blood count but not total disappearance of the myeloblasts. The dose of cyclophosphamide on the basis of body weight in this instance was not so great as in the other patients. The patient finally died of infection and hemorrhage 2.3 months later.

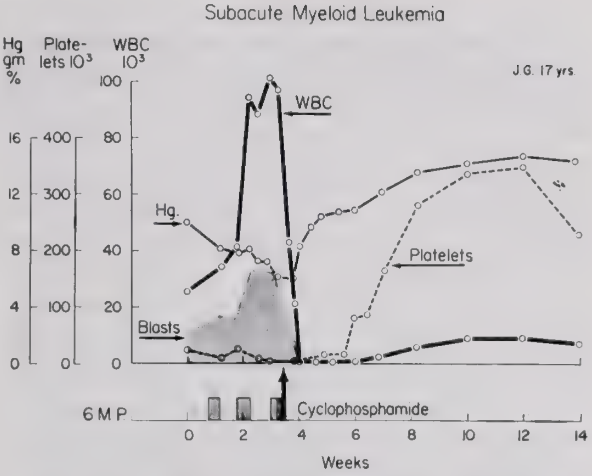

Fig. 1 — Case 5. Effect of combined therapy in a 17-year-old boy with subacute myeloid leukemia.

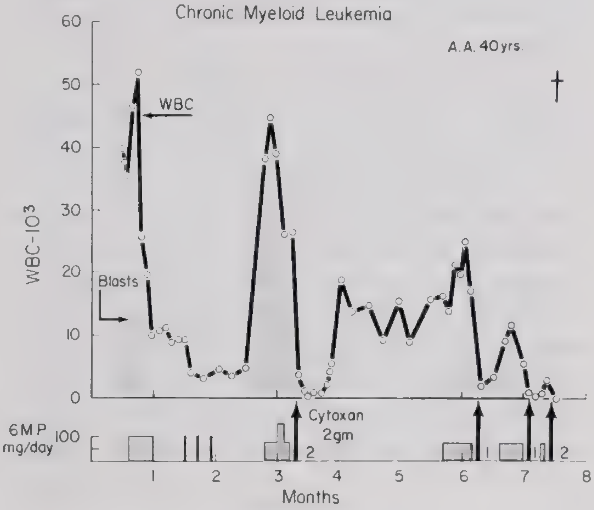

Fig. 2 — Case 8. Repeated courses of combined therapy evoked an antitumor effect.

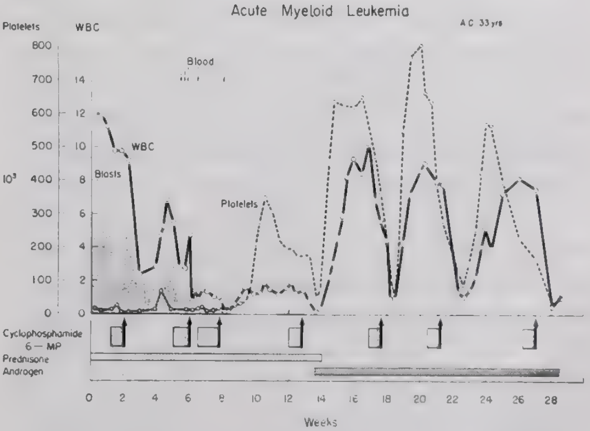

Fig. 3 — Case 4. Hematologic response to combined therapy in a patient with acute myeloid leukemia. The hemoglobin became normal.

Case 4

This 33-year-old woman had a three-month history of acute myelogenous leukemia which had been treated intensively with 6-mercaptopurine and prednisone. She was referred to the University Hospitals because of a lack of response to this therapy and the presence of thrombocytopenia. The total white blood count was 12,000 with 71 per cent myeloblasts. The platelet count was less than 20,000 per cmm. The patient was given a course of 6-mercaptopurine followed by cyclophosphamide, followed by an abrupt drop in the myeloblasts (Figure 3). Four weeks later, leukocytosis occurred and a second course of combined therapy was administered. Because of the persistence of blasts in the peripheral smear, a third course of therapy was given two weeks later. The white blood count decreased to levels below 1,000 cmm. and the platelets eventually increased to normal values. Testosterone enanthate 400 mg. three times a week intramuscularly was begun, and combined cytotoxic therapy was administered at monthly intervals with a gradual restoration of a normal hemoglobin and peripheral blood picture. Eight months after the initial course, the patient was asymptomatic with a complete bone marrow remission.

Of eight patients who received combination therapy for acute phases of myeloid leukemia, a decrease in total white blood count occurred in each instance. The hemoglobin rose in three patients and the myeloblasts decreased markedly in seven. A striking increase in thrombocytes occurred in three patients. A fourth patient may have demonstrated early evidence of this, but a cerebral vascular episode terminated the study. In two of the responding patients previous use of 6-mercaptopurine alone was not beneficial.

Discussion

Six-mercaptopurine has been utilized as a treatment of acute leukemia for more than ten years.[3] Cyclophosphamide has not been emphasized in the therapy of acute leukemia, although it has been used extensively in animal leukemias.[4] Hoogstraten reported the results of the Acute Leukemia Cooperative Group B with oral cyclophosphamide given at various dosage schedules,[5] but the drug was no better than placebos in prolonging survival and only slightly better than placebos in sustaining steroid induced remissions. The rate of administration seemed to make no difference; however, there was some suggestion that weekly doses were slightly more effective in maintaining remissions.

The rationale for combined chemotherapy has its foundation in the treatment of bacterial disease.[6] Studies on animal tumors have shown that the development of resistance to one chemotherapeutic agent may sometimes enhance susceptibility to another.[7] This is particularly true with the purine and folic acid antagonists. There is conclusive evidence that development of resistance to the purine analogs by bacteria and certain animal tumors is the result of enzymatic changes within the tumor cell. For 6-mercaptopurine resistance this change seems to involve a reduction in the amount of inosinic phosphorylase, thus providing a mechanism for the discovery of a synergistic drug.[8,9] Unfortunately this does not seem to be the mechanism of 6-mercaptopurine resistance in human leukemias. These findings have stimulated numerous trials with various combinations of agents. Six-mercaptopurine has been used in combination with methotrexate and azaserine,[10,11] but in both cases, the effect of the two drugs in combination was no greater than that expected for either of the two used separately.

In the present study, the short-term use of 6-mercaptopurine followed by a massive dose of cyclophosphamide produced a consistent decrease of white blood cells and myeloblasts. The most striking effect noted was the marked thrombocytosis which occurred in three patients. The platelet sparing effect of cyclophosphamide may be a factor in this phenomenon. A significant bone marrow remission occurred in two patients.

In two patients in whom massive androgen therapy was employed concomitantly with the cytotoxic therapy, a striking increase in hemoglobin occurred. This has been observed in the treatment of other conditions characterized by erythroid hypoplasia.[12] It would appear that sufficient leukemic elements of the marrow were destroyed to allow the normal cell precursors stimulated by the androgenic hormones to proliferate.

The action of cyclophosphamide is presumed to be similar to that of all the alkylating agents in that it destroys dividing cells more effectively than resting ones. The action of the alkylating agents on a cell involves a rather nonspecific effect due to the replacement of a hydrogen atom in a compound with an alkyl radical, with resultant denaturation of enzymes, chain rupture of nucleic acids, and cross-linking of DNA to itself and to its associated protein. The degree and type of damage is for the most part a function of the availability of the target. Like radiation, alkylating agents produce two types of cellular death.[13] The first is interphase death and results only when damage to the cellular proteins and nucleic acids has been extensive; a very high dose is required to kill a cell in this manner. The second type of death, mitotic death, occurs at a much lower dosage and is primarily due to damage to the chromosomes or the mitotic apparatus itself. This damage manifests itself at the time of division, but it may occur at any point in the cell cycle, although certain periods are more sensitive than others to injury. It is this second type of cell death that is utilized by both the radiotherapist and the chemotherapist. DNA and its associated proteins undergo rather marked alterations in their physiochemical state during the various stages of the cell cycle from the tightly clumped bands of chromatin in a mature nondividing cell to the filamentous, uncoiled strands of nucleoprotein in the primitive premitotic nucleus actively engaged in DNA synthesis. It is highly probable that the increased susceptibility to alkylating agents of cells engaged in premitotic DNA synthesis is a result of the increased availability of the uncoiled nucleoprotein for alkylation. Tissue sensitivity, in turn, is largely a function of the per cent of sensitive cells present; indeed, the mitotic index is generally accepted as an indicator of tissue sensitivity to alkylating agents. Any increase, therefore, in the per cent of sensitive cells in a tissue would be expected to result in an increase in the sensitivity of that tissue to alkylating agents.

Although 6-mercaptopurine is not incorporated into nucleic acids[9,14,15] it inhibits nucleic acid synthesis because of its metabolism through the usual pathways for anabolism and catabolism of the purine bases. It has been shown to inhibit at least four reactions: (1) the conversion of phosphoribosylpyrophosphate to 5-phosphoribosylamine; (2) the conversion of inosinic acid to adenylosuccinate; (3) the conversion of adenylosuccinate to adenylic acil; and (4) the conversion of inosinic acid to xanthylic acid.[16] These reactions are involved in the de novo synthesis of the purine bases, and when they are inhibited, the synthesis of nucleic acid is impaired unless the cell develops the capacity to depend exclusively on the salvage pathways as a source of preformed purines. This latter phenomenon has been observed in 6-mercaptopurine-resistant cells.[16] That 6-mercaptopurine may result in inhibition of DNA synthesis is evidenced clinically by the development of a megaloblastic bone marrow.[17] Treatment with 6-mercaptopurine would therefore be expected to produce a shift in the cell population of the bone marrow in such a way as to produce an increase in the per cent of cells in that stage of the cell cycle which has an increased sensitivity to alkylating agents. Pretreatment with 6-mercaptopurine, therefore, would be expected to greatly enhance the sensitivity of a cell population to cyclophosphamide.

Summary

Ten adults with acute myeloid leukemia were treated with combination therapy using a short course of 6-mercaptopurine and a massive dose of cyclophosphamide. There was a consistent reduction in white blood cells and myeloblasts. A marked thrombocytosis and an increase in hemoglobin were observed in three patients. A possible mechanism for the synergism of these two drugs is the ability of the 6-mercaptopurine to provide the alkylating agent with an increased number of susceptible cells.

The Sarsaparilla Era

Sarsaparilla is a medicinal preparation made from the root of smilax. Early in the nineteenth century a German physician thought that he had found it to be very valuable as a tonic and alterative. . . . On the strength of these clinical observations, physicians all over the world used sarsaparilla very commonly. It was sufficiently bitter and mediciny in flavor, as a rule, to make people realize that they were taking medicine, and many of them proceeded to get better, and most of them attributed their betterment to the sarsaparilla, but medical experience showed that there was no good reason to think so.

These sarsaparilla preparations were widely advertised. Every drug store in the country carried them in stock, but after a time so did every grocery store. There were literally millions of people in this country who swore by sarsaparilla. Many of them were quite sure that they had been sinking into an early grave and sarsaparilla had just taken them by the hand and lifted them up and given them renewed vigor, restored their appetite, regulated their bowels and given them back health and strength, and they were perfectly willing to tell all the world so.

The sarsaparillas had a wonderful effect upon the mind. The active ingredient in them was not the medicine on the inside of the bottle, but the printer's ink on the outside, and the still larger amount of printer's ink that was administered through the eyes of readers of the newspapers, the special advertising literature, the almanacs and the like which were issued, and the testimonials which were distributed. Great was sarsaparilla and great was its vogue, and now it is no more; only the memory of it remains, oh yes! and the fortunes that were made in its distribution, while sterling philanthropists took on themselves the task of doing the world good.*

Pulmonary Nocardiosis*

Report of Two Cases

WEN Y. YUE, M.D.**
SUMNER S. COHEN, M.D.**
Minnetonka, Minnesota

NOCARDIOSIS IS USUALLY a chronic, suppurative disease, but occasionally it runs an acute, fatal, fulminating course, manifesting itself by the involvement of the lungs, skin, brain, and other organs. The Nocardia organism is one of the soil-inhabiting Actinomycetaceae. There are at least 33 species; however, the most common pathogenic species, and the one usually responsible for nocardiosis in man, is Nocardia asteroides. The rare mycotic infection, caused by Nocardia, was first described in 1888 by Nocard,[1] who isolated the organism from cattle with farcy, and in 1890 by Eppinger,[2] who reported the first case of Nocardia meningitis.

Case Reports

Case 1

This 72-year-old white male, paraplegic for most of his life from undetermined cause, first noted cough, shortness of breath, and fever in June 1965. His chest film showed a pneumonic lesion in the upper lobe of the right lung which did not respond to treatment with penicillin. A subsequent film indicated a spread of his lesion with cavity formation.

He was admitted to Glen Lake State Sanatorium on August 2, 1965, because of suspected tuberculosis. Following admission he remained febrile with a temperature of 101° to 102°. His hemoglobin was 10 gm. and white blood cell count 27,000, with 86 per cent neutrophils. Skin tests, including tuberculin and histoplasmin and coccidioidin were negative. Sputum smears and cultures were negative for acid-fast bacilli and pathogenic fungi, but Candida and Staphylococci were present. A fluctuant mass, noted as a tumor, was found in his left anterior thigh.

The patient was treated with penicillin, streptomycin, chloromycetin, and ampicillin but showed no clinical response. Lumbar puncture was performed because he appeared semistuporous and showed signs of meningeal irritation; the spinal fluid revealed 1,700 cells, of which the great majority were polymorphonuclear leukocytes. Cultures of spinal fluid showed no growth of acid-fast bacilli, fungi, or other organisms. Gross hematuria appeared, but urine cultures grew only Candida and Pseudomonas aeruginosa. The fluctuant mass in the left anterior thigh was aspirated and a culture of the aspirated yellow pus grew Nocardia asteroides.

---

*From the medical department of Glen Lake State Sanatorium, Minnetonka, Minnesota.

**Specialists in chest diseases and tuberculosis.

Treatment with sulfadiazine, 12 gm. daily for two days, and then 6 gm. daily in divided doses, combined with tetracycline and mycostatin, began on August 30. Blood and spinal fluid levels of sulfadiazine were determined and showed the blood level to be 23 mg. per cent and the spinal fluid level, 13 mg. per cent. The patient's course slowly deteriorated, with progression of both cerebral and pulmonary conditions, until his death on September 9, 1965.

Autopsy disclosed Nocardia asteroides forming multiple, focal abscesses in the lungs, brain, right kidney, and subcutaneous tissue. Nocardia asteroides organisms were abundant in the involved tissue and demonstrated by culture. The brain showed a paraventricular white mass and some plaquing of gray matter, possibly due to multiple sclerosis.

Comment

This case illustrates the acute, fulminating nature of this disease. The diagnosis and treatment were perhaps instituted too late to alter the course. When there is cerebral involvement, the treatment becomes more difficult. It is interesting to note that repeated cultures of sputum, urine, and spinal fluid for fungi were negative. The pneumonic lesion with abscess not responding to intensive antibiotics and the subsequent involvement of brain and skin (subcutaneous abscess) led to suspicion of this rare disease.

Case 2

This 25-year-old Indian housewife was transferred from the Hennepin County General Hospital to Glen Lake State Sanatorium on June 24, 1952, with a history of good health until approximately one month before admission. At this time she experienced a sudden onset of sharp, pleuritic pain in the lower chest, associated with night sweats and a 12-pound weight loss. A roentgenogram made at General Hospital showed an extensive pneumonic type of infiltration of the upper lobe of the left lung suggestive of tuberculosis. Two sputum smears were positive for acid-fast bacilli, although cultures of the same specimens were negative. She was immediately put on a daily regimen of 1 gm. streptomycin sulfate and 12 gm. para-amino-salicylic acid.

On admission to the sanatorium she was found to have numerous small, shotty, nontender movable nodes in the anterior and posterior triangles of both sides of the neck. Skin tests were positive to old tuberculin (10 tuberculin units) and histoplasmin, but negative to coccidioidin and blastomycin. Laboratory study showed the hemoglobin to be 12.4 gm. and white blood cell count 10,150 with neutrophils, 81 per cent; lymphocytes, 9 per cent; monocytes, 1 per cent; eosinophils, 8 per cent; and basophils, 1 per cent. Sputum cultures were negative for acid-fast bacilli. Her chemotherapy, consisting of streptomycin and para-amino-salicylic acid, was continued.

By September her cervical glands began to enlarge and became painful and tender, and on September 15 a large cervical node was removed, which, on microscopic section, showed extensive necrosis. No tubercle bacilli were found by smears or cultures, but a fungus culture revealed growth of Nocardia asteroides. Bronchoscopy on December 31 showed a definite, ulcerative bronchitis involving the left main and lower lobe bronchi. The posterior and apical segments of the upper lobe of the left lung were removed on July 25. Microscopic section showed chronic, granulomatous inflammation with a necrotic area surrounded by fibrous tissue, some scattered giant cells, and one cluster of epithelioid cells. Tubercle bacilli and fungi were not found by culture or by guinea-pig inoculation. The patient deserted the sanatorium on February 24, 1954, and no follow-up information has since been available.

Comment

In this case Nocardia asteroides was cultured from the excised cervical lymph node. The pulmonary lesion may have been caused by Nocardia infection, although culture of sputum was negative for Nocardia. Because of the acid-fast property of Nocardia, this disease is often misdiagnosed as tuberculosis; however, coexistence of both diseases is possible. This patient recovered from this disease after treatment with pulmonary resection, excision of cervical glands, and chemotherapy for tuberculosis.

Discussion

Both Nocardia and Actinomyces belong to the soil-inhabiting Actinomycetaceae.[3] Nocardia is aerobic,* gram-positive, delicate, branching, and filamentous; some species are acid-fast and may be confused with tubercle bacilli. The filaments are seldom, if ever, visible with the hematoxylin and eosin stain but are easily visible with the Giemsa stain or one of the modifications of the gram stain. Nocardia grows slowly on all common laboratory media and should be differentiated from tubercle bacilli and Actinomyces.

Peabody and Seabury[4] pointed out that the recovery of this organism sometimes is most difficult to interpret; an occasional colony may occur as a contaminant or saprophyte; but numerous colonies or repeated isolations of the organisms are more significant. Demonstration of this organism in tissue, by cultural and histologic methods, is positive evidence of this disease. Nocardiosis is usually considered to be an exogenous infection; is caused by a fungus present in the soil; and has an incidence evenly distributed over the world, with no racial preference, but higher in men than in women. Preponderance of pulmonary involvement suggests that the respiratory tract is the portal of entry. Nocardiosis has occurred following dental extraction, and the alimentary tract as a portal of entry has also been emphasized.[5,6]

---

*See Test Your Word Score Page 1107.

The clinical and radiologic features are variable and nonspecific and may resemble those of tuberculosis, pneumonia, lung abscess, mycotic infections, and other conditions. The main clinical signs and symptoms are cough, yellow sputum, fever, night sweats, and pulmonary consolidation or abscess. Radiologic features are the dense areas of lobular or lobar consolidation and areas of rarefaction resembling lung abscess, with or without pleural reaction. The pathologic process takes the form of abscesses in the lungs, brain, lymph nodes, skin (subcutaneous tissue), and other sites. The primary site is frequently in the lungs. The histologic picture is that of extensive necrosis of tissue with a marked surrounding cellular reaction but no fibroblastic reaction.

Diagnosis

Although the organisms can be identified easily with proper stains, the diagnosis of nocardiosis cannot be made by histologic examination alone. The demonstration of the organism by culture from proper materials and tissue is the only confirmative laboratory procedure. The differential diagnosis includes: tuberculosis; mycotic infections, such as histoplasmosis, blastomycosis and actinomycosis; bronchogenic carcinoma, especially with intracerebral metastasis; bacterial pneumonia; lung abscess; and others. Coexistence of this disease with others or this disease superimposed upon other grave diseases is a distinct possibility. When acute pneumonia or subacute pneumonia does not respond to regular antibiotic therapy and progresses to lung abscess and meningeal involvement, nocardiosis should be suspected.

Treatment

Treatment is chiefly medical, but may be supplemented by drainage and excision of abscess or empyema. Sulfadiazine, given in divided doses of 4 to 6 gm. daily, remains the drug of choice.[7-9] Nocardiosis can be treated and controlled; therefore, early recognition is of paramount importance. Early administration of a specific antibiotic may be lifesaving and may prevent the spread of the organisms to the central nervous system with the subsequent crippling effects. With prompt diagnosis, prognosis is good; but fulminating cases with brain abscess or cases in which nocardiosis is superimposed upon another grave disease have a very poor outlook. The Nocardia organism should be tested to determine sensitivity to sulfadiazine as well as to other broad-spectrum antibiotics. Peabody and Seabury[10] suggested the daily use of 4 gm. of sulfadiazine and 2 gm. of a broad-spectrum antibiotic. Treatment should continue for several months after clinical manifestations have cleared, before the patient is considered cured.

Summary

This is a report of two cases of pulmonary nocardiosis, emphasizing the importance of early recognition of this treatable infection. Nocardiosis is usually a chronic, suppurative disease, but occasionally it runs an acute, fulminating course. The primary infection is usually in the lungs, with metastatic lesions to the brain, skin, (subcutaneous tissue), and other sites. It is caused, in almost all cases, by Nocardia asteroides. Pneumonic processes which do not respond to antibiotics and which progress to abscesses or spread to the central nervous system should suggest this rare disease. Prognosis is favorable, provided diagnosis is early and specific treatment is begun. Treatment is mainly medical, with sulfadiazine as the drug of choice. Surgical treatment consists of drainage or excision of abscesses.

Gulliver's Travels — Jonathan Swift*

Gulliver — On the Virtues of Living in an Island Without Man

Gulliver had now lived for five years on the island where the horse was the master and found the experience very gratifying.

"No man could more verify the truth of these two maxims: that nature is very easily satisfied; and, that necessity is the mother of invention. I enjoyed perfect health of body and tranquillity of mind; I did not feel the treachery or inconstancy of a friend, nor the injuries of a secret or open enemy. I had no occasion of bribing, flattering or pimping, to procure the favor of any great man, or of his minion. Here was neither physician to destroy my body nor lawyer to ruin my fortune; no informer to watch my words and actions, or forge accusations against me for hire; here were no jibers, censurers, backbiters, pick-pockets, highwaymen, house-breakers, attorneys, bawds, buffoons, gamesters, politicians, wits, spleneticks, tedious talkers, controvertists, ravishers, murderers, robbers, virtuosos; no dungeon, axes, gibbets, whipping posts or pillories; no cheating shop-keepers or mechanics; no pride, vanity or affectation; no fops, bullies, drunkards, strolling whores, or poxes; no ranting, lewd, expensive wives; no stupid, proud pedants; no importunate, over-bearing, quarrelsome, noisy, roaring, empty, conceited, swearing companions; no scoundrels raised from the dust upon the merit of their vices; or nobility thrown into it on account of their virtues; no lords, fiddlers, judges, or dancing masters."

The Autopsy of Samuel Johnson

On opening into the cavity of the chest, the lungs did not collapse as they usually do when air is admitted, but remained distended, as if they had lost the power of contraction; the air-cells on the surface of the lungs were also very enlarged; the right lobe adhered very strongly to the diaphragm; the internal surface of the trachea was somewhat inflamed; no water was found in the cavity of the thorax. The heart was exceedingly large and strong, the valves of the aorta were beginning to ossify; no more fluid than was common was contained in the pericardium. In the abdomen seemed to be incipient peritoneal inflammation and ascites; the liver and spleen were firm and hard; the spleen had almost the feel of cartilage. A gall stone about the size of a pigeon's egg was taken out of the gall bladder; the omentum was exceedingly fat; nothing remarkable was found in the stomach; the folds of the jejunum adhered in several places to one another; there was also a strong adhesion by a long slip between the colon and bladder; the pancreas was remarkably enlarged; the kidney of the left side tolerably good, some hydatids beginning to form on its surface; that of the right side was almost entirely destroyed, and two large hydatids formed in its place. (Dr. Johnson never complained of any pain in this part; the left testicle was perfectly sound in structure, but had also a number of hydatids on its surface, containing a fatty gelatinous fluid, the right testicle had hydatids likewise, but the spermatic vein belonging to it was exceedingly enlarged and varicose.) The cranium was not opened.

— James Wilson (1725-1821)

Erythroblastosis Fetalis

Management at the University of Minnesota Hospitals

LEON L. ADCOCK, M.D.[*]
Minneapolis, Minnesota

MUCH PROGRESS in the clarification of the etiology and pathophysiology of erythroblastosis fetalis has been made in relatively recent years. Although various forms of the disease — hydrops fetalis, icterus gravis neonatorum and hemolytic anemia of the newborn — have been known for a long time,[1] it was not until 1932 that these conditions were shown to be the result of the same disease.[2] In 1940 Landsteiner and Weiner[3] reported the discovery of the Rh antigen; its importance in the etiology of erythroblastosis fetalis was emphasized by Levine et al.[4] one year later.

It has been well established that the transplacental passage of fetal erythrocytes occurs commonly during normal pregnancy. The number of such erythrocytes present in the maternal circulation during pregnancy is increased in some complications such as abruptio placentae and toxemia, as well as a result of operative obstetric procedures such as cesarean section, forceps delivery and manual removal of the placenta.[5,6] However, there is no unanimity of opinion concerning this problem.[7]

Rh antibodies of small molecular size formed in the mother readily pass the placenta to the fetus and attach to the Rh substance of fetal erythrocytes. The life span of these affected erythrocytes is decreased by hemolysis from a normal of 100 to 200 days to approximately 10 days. The fetus may or may not successfully combat the resultant anemia, although the excess bilirubin released by the hemolysis is efficiently excreted through the placenta.

---

[*] Department of Obstetrics and Gynecology, University of Minnesota Medical School.

Clinical Management

The clinical problem is one of management of the affected infant. At the present time there is no available method of preventing maternal sensitization, although very promising studies are in progress.[8,9] Attempts at destruction or modification of the antibodies have been unsuccessful. Methods for increasing the capacity of the fetus to produce erythrocytes are not yet available.

Timing of Delivery

Selection of patients and proper timing of delivery will result in improved over-all results. Premature delivery is fraught with hazard; but a compromise in fetal maturity may be necessary as the severity of the hemolytic disease increases. Premature delivery of an unaffected or mildly affected infant that does not survive is tragic, but equally tragic is the loss of a mature infant with erythroblastosis fetalis who might have survived with earlier delivery and exchange transfusion. The major obstacle in early delivery has been the inability to predict the severity of the fetal disease.

The management of the Rh negative patient is based on careful evaluation during pregnancy. Rh antibodies must be detected if present. Once a patient is known to be immunized, the status of the fetus in utero must be evaluated. The fetus may be Rh compatible and not affected or may be Rh positive and have hemolytic disease. In the latter situation the severity of the disease must also be assessed.

The methods commonly used to evaluate a current pregnancy are the past obstetrical and transfusion history, the antibody titers, the present prenatal course, and the husband's Rh zygosity.

The Husband's Genotype

Determination of the husband's genotype is of obvious value. Although the probability of the Rh positive husband's heterozygosity can be estimated, it cannot be serologically proven, because the anti-d (Hr^o) antigen is not available. An Rh negative child or parent confirms the husband's heterozygosity but is of no value in assessing the severity of hemolytic disease of the Rh positive fetus in utero.

Impending Fetal Death

Occasionally there are indications during the prenatal course that fetal demise is impending. A sudden decrease in fetal movement or the "toxemia syndrome," characterized by edema, rapid weight gain, hypertension, proteinuria and generalized pruritus may occur. Unfortunately by this time the fetus is usually hydropic and salvage is rarely possible.

Spectrophotometry

Because the evaluation of the status of the fetus in utero by history of previous pregnancies and the level of maternal antibody titers in the current pregnancy were not always reliable, Bevis[10] pioneered the study of the composition of amniotic fluid and in 1956 introduced the spectrophotometric analysis of amniotic fluid. He utilized the information obtained from these studies to estimate the degree of fetal affectation prior to delivery. In 1961 Liley[11] reported his method of evaluating the spectral absorption curve of amniotic fluid. Using logarithmic* values, he plotted the optical density of the additional absorption at 450 millimicrons on the ordinate and the duration of gestation on the abscissa of a graph. On this graph zones were delineated which corresponded to the degree of fetal disease. Serial amniotic fluid examinations resulted in improved evaluation of the degree of fetal hemolytic disease. This technique is now widely used and its value is established.

Present Report

In order to correlate some of these factors

with the fetal outcome the records of Rh negative patients delivered at the University of Minnesota Hospitals from January 1956 to April 1965 have been reviewed. Of approximately 800 Rh negative patients who were delivered, 104 (13%) had serum with Rh antibodies. Five of these patients were sensitized by blood administration prior to pregnancy. Nineteen (18.2%) delivered one or more Rh compatible infants.

The Sensitized Mothers

The 104 sensitized patients delivered a total of 131 infants. Twenty-two infants were Rh compatible, and nine were Rh incompatible but did not have hemolytic disease, as the cord blood direct Coombs test was negative. The latter group is difficult to explain, but the avidity of Rh antibodies for the antigen varies, particularly when the titer is low.[12] The Coombs test could have been so weakly positive that it was not detectable. Laboratory error cannot be completely excluded. One hundred infants (76.3%) were Rh incompatible and had erythroblastosis fetalis. The severity of the disease among these infants is shown in Table 1. Three of the fetal deaths in utero were associated with fibrinogenopenia of clinical significance.

The Iso-immune Infants

The over-all results of the 131 infants delivered of Rh sensitized patients are seen in Table 2. The perinatal* mortality rate of the 100 infants with erythroblastosis fetalis was 26%. Of the 27 infants who did not survive, 21 died in utero from the disease or were hydropic and unsalvageable at birth. This finding demonstrates dramatically the need to determine the severity of the hemolytic disease in utero if increased salvage of these infants by intrauterine transfusion and/or early delivery prior to the development of hydrops is to be accomplished. Intrauterine fetal transfusion, as first described by Liley,[13] may be necessary one or more times to enable some fetuses to survive and mature sufficiently to decrease the risk inherent to early delivery.

Previous Pregnancies

The outcome of previous pregnancies has been shown to be an important factor in estimating the outcome of a current pregnancy[14] (Table 3). Of those patients who bore infants with the severest form of the disease in a previous pregnancy (fetal death in utero) three delivered Rh compatible infants, six delivered infants with mild or moderate disease, three delivered infants with severe disease, and nine delivered hydropic or stillborn infants. Of the 57 patients who had not previously delivered an infant with erythroblastosis fetalis, 10 delivered infants with severe disease and only four experienced fetal death in utero.

Rh Antibody Titer

The level of the maternal Rh antibody titer is also used to estimate fetal prognosis. The outcome of the first pregnancy in which an indirect Coombs antibody titer was dem-

5. Fetal death in utero	15	0	15	100%
D. All infants delivered by RH ISO-Immunized patients	131	12	15	20.6%

onstrated is correlated with the highest maternal titer in that pregnancy (Table 4). Although there is a definite trend toward more severely affected infants among patients with higher titers, a number of less severely affected infants were delivered when the titers were high. There was no severely affected infant when the highest titer was 1:16 or less and only one when the titer was 1:32. The trend of serial antibody titers in the first sensitized pregnancy is therefore of some value. The correlation between severity of the hemolytic disease in the infant and the height of the titer when antibodies had been demonstrated in preceding pregnancies is presented in Table 5. Although the same trend is seen, it is of less prognostic value when compared to the titer level in the first demonstrably sensitized pregnancy.

Method of Delivery

One hundred eighteen infants were delivered vaginally. Seventy-two of these were delivered after the spontaneous onset of labor and 12 (16.6%) did not survive. Labor was induced in 46 instances with nine (19.5%) perinatal deaths. Of these 21 infants that did not survive, 15 were dead in utero and three were hydropic at birth. Only three of the 43 moderately or severely affected infants were lost after vaginal delivery. Cesarean section was performed on 13 occasions with erythroblastosis fetalis as the sole indication. Although five of these infants did not survive, three were known to be hydropic, and operation was performed in an heroic attempt to salvage the infants. One Rh negative infant weighing 2125 grams was delivered by cesarean section at 35 weeks' gestation and died of respiratory distress syndrome. The mother of this infant had previously delivered three stillborn infants. Although amniotic fluid studies had been performed, they wrongfully suggested severe affectation. The correlation between survival, severity of the disease, and the mode of delivery is presented in Table 6.

Nineteen patients in the series were admitted for delivery who were not registered in the prenatal clinic and 12 of their infants did not survive.

The Birth Weight

The birth weight of the infants is of great significance as related to survival. Nine infants were delivered who weighed less than 1500 grams and none survived. Four infants weighed between 1500 and 2000 grams. Two of these infants with hemolytic disease survived but neither required exchange transfusion. Of 16 infants who weighed from 2000 to 2500 grams five were hydropic or stillborn. Ten infants survived following one or more exchange transfusions. The last was the 2125-gram Rh negative infant previously discussed. Of 102 infants that weighed more

*Sensitized by RH Incompatible Blood Administration (E.F., erythroblastosis fetalis; N.N.D., neonatal death; F.D.I.U., fetal death in utero) than 2500 grams, 10 did not survive. Five of these were stillborn and one was liveborn but hydropic and did not survive. The other four died of severe hemolytic disease despite one or more exchange transfusions.

Duration of Gestation

Of interest is the duration of gestation at the time of delivery or fetal death in utero of the 21 infants who were stillborn or liveborn with hydrops fetalis. These findings together with the registered or unregistered status of the mother are presented in Table 7. Eleven patients with fetal death in utero had not been registered in the prenatal clinic of the University of Minnesota Hospitals. One registered patient with fetal death in utero at 36 weeks' gestation had abruptio placentae and toxemia. The infant was not hydropic. Two other registered patients had delivered stillborn infants weighing 2080 and 2205 grams. Fetal death occurred in one patient prior to 24 weeks' gestation.

All the patients who delivered liveborn hydropic infants were registered. Four of these infants weighed under 2000 grams, one weighed 2400 and another 2500 grams. Cesarean section was performed on three of the patients after 31 weeks' gestation and labor was induced in one patient.

It appears from this table that among the registered patients, two of the infants that died in utero and all of the six hydropic infants might have been salvaged at the present time with intrauterine fetal transfusion.

D (Rh°) occurred in nine patients, although anti-D was also present in four. When sensitization to two or more factors was present, the anti-D sensitization was probably the more significant (Table 8). Of significance is the fact that three patients were D(Rh°) positive but were sensitized to c (hr′). These patients delivered seven infants who were acutely ill. This experience demonstrates the need for additional screening to identify the less common antibodies in the Rh positive patient if an obstetrical history indicates that a previous infant developed neonatal jaundice.

Amniotic Fluid Evaluation

Studies of amniotic fluid pigment are now commonly utilized to evaluate the severity of fetal hemolytic disease. Transabdominal amniocentesis to obtain fluid for analysis is indicated when the maternal antibody titer is 1:32 or greater. Although this procedure is usually performed at 31 or 32 weeks' gestation it may be done as early as 24 weeks when fetal death in utero has occurred in a previous pregnancy. Subsequent amniotic fluid samples are drawn at two to three-week intervals and determinations made to establish a trend in the height of the peak at a wavelength of 450 millicrons due to "bilirubinoid" pigments.

Technique

Transabdominal amniocentesis is not a difficult procedure but should be done with sterile technique. The patient's bladder should be empty and the fetal position determined. The site of the puncture in the region of the fetal small parts one or two inches from the midline is injected with a local anesthetic solution. A five to eight-inch 20-gauge needle with a stylet is introduced

through the abdominal and uterine walls. The placenta should be avoided if possible. Approximately 10 milliliters of amniotic fluid is withdrawn and transferred to a sterile tube. The fluid should be protected from light and ideally should not be contaminated with blood. It should be centrifuged within two hours or immediately if it contains blood. The supernatant fluid should be filtered using Whatman No. 5 or S & S 597 filter paper. It can be stored at room temperature and sent in the mail for analysis if necessary.

Complications

Amniocentesis fails in about 5 to 10% of the attempts. Blood is obtained in almost 50%.[15] When blood is obtained, an Rh determination and direct Coombs test are performed. Fetal erythrocytes are identified by the acid elution technique.[5] At least 10 days should be allowed after a bloody tap before amniocentesis is repeated. Serum, especially that from an affected fetus, will enlarge the optical density peak at 450 millimicrons. Meconium is rarely encountered early in gestation but when present has a slightly different absorption wave length. The injection of a radio-opaque medium and a dye aid in obtaining fluid from each amniotic sac in a twin pregnancy.[16] Intestinal atresia and anencephaly increase the bilirubin content of amniotic fluid.[17]

Occasional complications of amniocentesis have been reported. Amnionitis has been encountered by Liley.[21] Fairweather[15] noted episodes of hyperpyrexia in his patients, the etiology of which was not determined. Premature delivery may occasionally follow amniocentesis. An increase in antibody titer following amniocentesis has been reported.[18,19] This is due to disruption of the fetal-maternal placental circulation but ordinarily does not affect the prognosis for the fetus or for infants of subsequent pregnancies.[20] Nevertheless, amniocentesis should not be performed without sufficient indication.

Case Reports

Two case reports are presented to demonstrate the value of amniotic fluid findings in the management of individual patients with Rh isoimmunization.

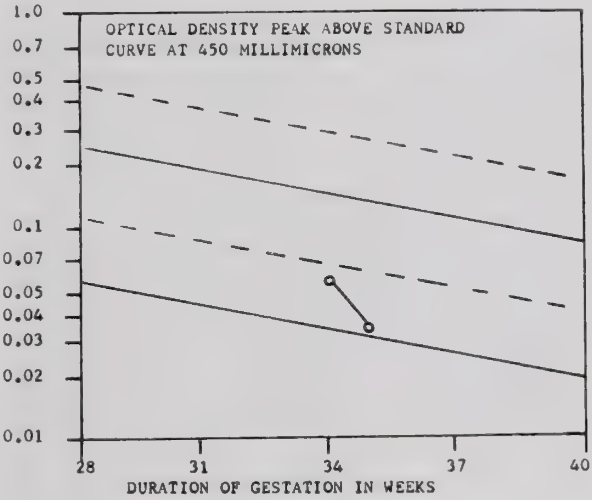

Fig. 1
Amniocentesis at 34 and 35 weeks' gestation. Pitocin induction of labor at 37 weeks. Infant — 3425 grams, blood group AB, CDe/c; direct Coombs +. Cord blood — HGB 15.1 gm%, bilirubin 5.7 mg%. Three exchange transfusions. Highest serum bilirubin 26.3 mg% on third day.

TABLE 8
RH ISO-Immunization
Sensitization to Factors Other Than D (RH_0)

		Severity of Disease				
RH Factors	Patients	RH Negative	Mild	Moderate	Severe	Hydrops Fetalis
D, C, E (Rh_0, rh′, rh″)	1	1	0	0	0	0
c (hr′)	3	0	0	4	2	1
E (rh″)	1	0	2	0	0	0
D, C (Rh_0, rh′)	3	0	0	1	2	0
e (hr″)	1	0	1	0	0	0

Case 1

A 42-year-old para 5-0-0-5 patient was blood group A, cde. Her husband was blood group B, CDE. Her first four infants were unaffected and all were CDe/c. In 1956, during her fifth pregnancy, antibodies were detected for the first time. The highest titer was 1:128. Spontaneous labor occurred at 41 weeks. The infant was severely affected. The cord hemoglobin was 5.4 grams per cent. Two exchange transfusions were performed; the infant survived and is normal. During her sixth pregnancy in 1963 the highest indirect Coombs titer was 1:256. Amniotic fluid was obtained at 34 and 35 weeks' gestation and the findings recorded in the manner described by Liley are shown in Figure 1. The values are in the middle zone indicating moderate hemolytic disease. In spite of the history of a previously severely affected infant the pregnancy was allowed to progress to 37 weeks' gestation. The infant survived with three exchange transfusions.

Case 2

A 35-year-old para 5-0-0-4 patient was blood group O, cde and her husband was blood group A, CDE/c. One parent of the husband was cde. The first two infants were Rh positive. The second was severely affected but survived with kernicterus. In 1959 a hydropic infant with a cord hemoglobin of 2.8 grams per cent was delivered after induction of labor at 36 weeks' gestation but did not survive. In 1961 labor was induced at 36 weeks and an Rh negative infant weighing 3590 grams was delivered. Another Rh negative infant was delivered in 1963. In 1965 the indirect Coombs titer was 1:1024 at 16 weeks and dropped to 1:256 at 32 weeks' gestation. Amniotic fluid was obtained at 34 and 38 weeks (Figure 2). Spectrophotometric analysis of the amniotic fluid showed lower zone values, and an Rh negative infant was delivered at term.

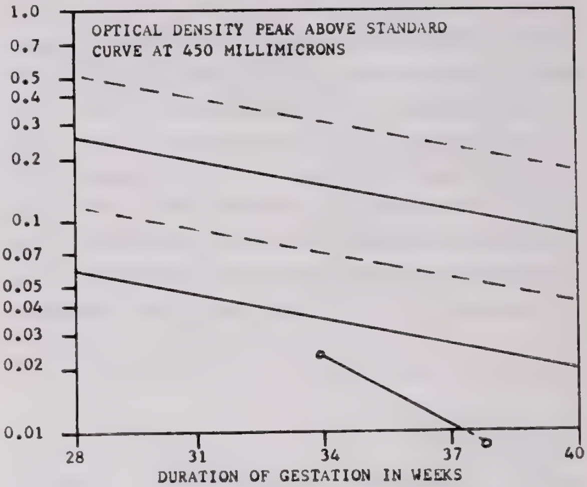

Fig. 2

Amniocentesis at 34 weeks and 38 weeks. Elective induction of labor by amniotomy at 39 weeks. Infant — female, 3580 grams, blood group O, cde, direct Coombs neg. Cord blood — HGB 18.8 gm%, bilirubin 2.2 mg%.

Summary

The obstetrical history, the Rh antibody titers, the prenatal course, and the Rh genotype of the husband provide only minimal information concerning the severity of the hemolytic disease of the fetus in utero.

Amniotic fluid analyses are of great value to identify Rh negative unaffected fetuses and to evaluate the severity of the hemolytic disease when present.

Preterm and premature delivery with immediate exchange transfusion can salvage a large proportion of infants who otherwise would be stillborn or liveborn with hydrops fetalis.

In a small number of selected patients, perhaps 5 to 8%, intrauterine fetal transfusion may be necessary to allow the fetus to achieve adequate maturity prior to delivery.

Chronic Obstructive Airway Disease

Improvement in Pulmonary Function after Vigorous Program

DAVID E. DINES, M.D.*
Rochester, Minnesota

ALTHOUGH PULMONARY function may be of prognostic value in chronic obstructive airway disease,[1] rarely is improvement—as evidenced by results of a battery of pulmonary function tests—seen after vigorous treatment. The follow-up response to treatment of patients with such a condition is so often discouraging that it seems worthwhile to present a case in which significant objective improvement in pulmonary function was demonstrated after one year of therapy.

Case Report

A 68-year-old man was seen at the Mayo Clinic on August 31, 1964, because of progressive dyspnea and chronic cough of six years' duration. Besides smoking two packs of cigarettes every day for 49 years, he had been in the upholstering business for 40 years where he was exposed to dust and to fumes from lacquers. He had a long history of asthma with upper respiratory infections during the winter that dated back to childhood. His chronic cough had been productive of 2 oz. of clear sputum every day for 28 years. In addition, cold air, dust, fumes, and chemicals caused bronchospasm.

On examination he had dyspnea of grade 3. Breath sounds were diminished in the bases, and there were inspiratory and expiratory wheezes. There was expiratory slowing of grade 4 and the diaphragm moved only 1 cm. bilaterally. Chest expansion was limited to 1.5 cm.

A chest roentgenogram was interpreted as showing emphysema. There was a normal flora on routine sputum culture.

Pulmonary function tests on August 25, 1964, (Table) showed severe obstructive airway disease. There was an increase in the residual volume and in the ratio of residual volume to total capacity. The maximal breathing capacity was decreased considerably, and the maximal midexpiratory flow was only 0.4 liter per second. The nitrogen-washout index was elevated to 6.7%. The patient was desaturated at rest and became more desaturated after only 1.3 minutes of exercise, which was all he could tolerate.

A program of treatment for emphysema was initiated. This program included the drinking of 10 to 12 glasses of water each day, breathing exercises, and instruction in a dust-free room. He was instructed in the use of a nebulizer (Isuprel 1:200, 10 drops with 10 drops of distilled water three times a day). One bronchodilator tablet three times a day, one hour after the nebulizer, was prescribed. He was instructed to use tetracycline, 250 mg. four times a day for five days, when upper respiratory infection was noted or when his sputum was discolored.

---

*Mayo Clinic and Mayo Foundation: Section of Medicine, Rochester, Minnesota.

The patient returned on August 18, 1965, for a recheck of the chronic obstructive airway disease. He had been feeling well and was active physically, walking six blocks a day. He did not cough excessively and was averaging only ½ oz. of clear sputum per day. He had had no bronchial infections during the preceding year. On this examination (one year after the initial one) his chest expansion had increased to 3.8 cm. (1½ inches); his diaphragm moved 2 cm. bilaterally and the expiratory slowing was grade 2. The chest roentgenogram was interpreted as normal.

At this time the patient's vital capacity and maximal breathing capacity had increased and the nitrogen-washout index had decreased. There was less expiratory slowing, as shown by the maximal midexpiratory flow before and after the nebulizer was used (Table). The patient now has a normal arterial oxygen saturation at rest and after five minutes of exercise.

Discussion

A correlation has been found between the severity of emphysema at autopsy and the premortem values of vital capacity, maximal voluntary ventilation, and maximal midexpiratory flow rates.[2] Sweet and associates,[3] in an earlier publication, described a correlation between the ratio of residual volume to total capacity (RV/TC) and the morphologic findings of emphysema at autopsy. Boushy and Coates[4] have found four parameters of pulmonary function related to prognosis (maximal voluntary ventilation, forced vital capacity, carbon dioxide tension, and oxygen saturation). Abnormal tensions of arterial blood gas have been postulated as being related to prognosis[5] and of value in determining the onset of cor pulmonale.[6] Other workers[7] have stated that abnormalities of blood gas reflect the severity of the illness primarily in acute

Average tidal volume, ml.		627	747

*Values after treatment with Isuprel given in parentheses.

exacerbations. Chronic hypercapnia* is common in patients with chronic obstructive airway disease. Although the degree of carbon dioxide retention[8] reflects the severity of the acute illness, it still may be of prognostic value when combined with the RV/TC ratio, maximal breathing capacity, maximal midexpiratory flow, nitrogen-washout index, and arterial oxygen saturation. A vital capacity, maximal breathing capacity, and maximal midexpiratory flow before and after nebulization give an excellent index of the response to therapy. The failure of a response at the beginning of treatment, however, does not obviate the benefit from bronchodilators, as is shown in this case. The patient should be retested after he has been on a treatment program for several months.

Summary

A vigorous approach to chronic obstructive airway disease can bring about improvement in the pulmonary function. Herein is reported a case of a 68-year-old man who experienced significant improvement subjectively and objectively after one year of treatment consisting of a high fluid intake and breathing exercises, medication with expectorants, nebulizers, bronchodilators and intermittent antibiotics.

Faxen's Syndrome

This eponymic term has been used to designate certain aberrations of behavior and body movements. The syndrome is characterized by playful and manneristic behavior, iteration, retropulsion, rigidity, and turning about the longitudinal axis. Although these abnormal activities are more often associated with schizophrenia, they may also occur as a manifestation of an encephalopathic complex that results from severe, prolonged periods of alcoholism. If the symptoms of the Faxen syndrome are relatively mild, the patient may recover. More serious cases may progress to a stage of cerebral degeneration.

Derivatively Speaking

Telangiectasis — from Greek *tele* (at a distance) plus *angeion* (vessel) plus *ektasis* (dilatation)

in diarrhea

LOMOTIL® Tablets Liquid

Each tablet and each 5 cc. of liquid contains:
diphenoxylate hydrochloride . . . . 2.5 mg.
(Warning: May be habit forming)
atropine sulfate . . . . 0.025 mg.

is a corker

Effectiveness: Lomotil possesses a unique degree of effectiveness in both acute and chronic diarrhea.

Convenience: Lomotil is supplied as small, easily carried, easily swallowed tablets and as a pleasant, fruit-flavored liquid.

Versatility: The therapeutic efficiency, safety and convenience of Lomotil may be used to advantage alone or as adjunctive therapy in diarrhea associated with:

- **Ulcerative colitis**
- **Acute infections**
- **Irritable bowel**
- **Regional enteritis**
- **Drug therapy**
- **Food Poisoning**
- **Functional hypermotility**
- **Malabsorption syndrome**
- **Ileostomy**
- **Gastroenteritis and colitis**

Dosage: For full therapeutic effect – Rx full therapeutic dosage. The recommended initial daily dosages, given in divided doses, until diarrhea is controlled, are:

Children:	3 to 6 months	– 3 mg. (½ tsp.* t.i.d.)
	6 to 12 months	– 4 mg. (½ tsp. q.i.d.)
	1 to 2 years	– 5 mg. (½ tsp. 5 times daily)
	2 to 5 years	– 6 mg. (1 tsp. t.i.d.)
	5 to 8 years	– 8 mg. (1 tsp. q.i.d.)
	8 to 12 years	–10 mg. (1 tsp. 5 times daily)
Adults:	20 mg. (2 tsp. 5 times daily or 2 tablets 4 times daily)	

*Based on 4 cc. per teaspoonful.

Maintenance dosage may be as low as one-fourth the therapeutic dose.

Precautions: Lomotil, brand of diphenoxylate hydrochloride with atropine sulfate, is a Federally exempt narcotic preparation of very low addictive potential. Recommended dosages should not be exceeded. Lomotil should be used with caution in patients with impaired liver function and in patients taking addicting drugs or barbiturates. The subtherapeutic amount of atropine is added to discourage deliberate overdosage.

Side Effects: Side effects are relatively uncommon but among those reported are gastrointestinal irritation, sedation, dizziness, cutaneous manifestations, restlessness, insomnia, numbness of extremities, headache, blurring of vision, swelling of the gums, euphoria, depression and general malaise.

P·B·SAL·C
NON-HORMONAL ANTI-ARTHRITIC

Helps keep arthritic patients active

P-B-SAL-C is a dependable, effective salicylate formula for relief of pain due to rheumatoid arthritis, bursitis and fibrositis.

Its formula consists of a combination of sodium salicylate, para-aminobenzoic acid and ascorbic acid. This special combination provides higher, longer-lasting analgesic levels compared with salicylates alone. Each P-B-SAL-C Tablet is enteric coated to delay disintegration until it reaches the small intestine.

P-B-SAL-C, low in cost to your arthritic patients, will help keep them active. Other P-B-SAL-C formulas available:

1. P-B-SAL-C with Colchicine
2. P-B-SAL-C with Esoprine
3. P-B-SAL-C Sodium Free
4. P-B-SAL-C with Prednisolone (Sodium Free)

For complete information and samples, write to Dept. MM-105

FORMULA

Each enteric-coated P-B-SAL-C Tablet contains sodium salicylate 0.3 Gm., para-aminobenzoic acid 0.3 Gm., ascorbic acid 50.0 mg.

CONTRAINDICATIONS

Renal damage, salicylate sensitivity or in conjunction with sulfonamide therapy.

DOSAGE

Take 2 tablets four or more times daily.

When the Cervical Pap Smear is Positive

ELSEWHERE IN THIS issue* is a resumé of a forum on the positive Pap smear presented at the last clinical meeting of the Minnesota State Medical Association.

That differences of opinion exist is not surprising, since the procedures followed are relatively new. One author's opinion is expressed as follows: "Tissue must be procured from the entire circumference of the junctional zone. Instrumentation, even the taking of office biopsies, may destroy the histologic evidence of early lesions." Just two paragraphs later the opinion is given that multiple cervical biopsies taken in the office are mandatory after a positive smear test. This writer has used both approaches. In earlier practice, office biopsies of the cervix were routine after a confirmedly suspicious or a positive smear test, even though the cervix appeared normal. This practice was later discarded because the yield of invasive carcinoma was nil, and the presence of intraepithelial carcinoma in the punch biopsies did not obviate the need for later conization to rule out invasive carcinoma elsewhere in the portio or canal. Another advantage of the more immediate approach, that of hospitalization and conization, is to cut short the suspense factor in the anxious patient. The authors point out, however, that sufficient time should be taken to treat vaginal infections and repeat suspicious smears to avoid the consequences of false positives.

The article states that total hysterectomy and intracavitary radium therapy are both acceptable forms of treatment in the young patient with carcinoma in situ. Here again is a debatable field. No doubt exists, however, that the surgical approach has an overwhelming majority of proponents, especially for the young woman in whom childbearing is completed. The surgically treated patient has both the psychological benefit of having the lesion-bearing organ extirpated and the advantage of avoiding symptoms of irradiation castration.

Treating young women with an intravaginal cone with kilovoltage techniques plus surgical replacement of the ovaries laterally is a new and interesting concept. This does not seem necessary, however, for the young woman who is willing to appear at regular intervals for smear testing and pelvic examination after a conservative conization biopsy removal of the in-situ lesion. When residual carcinoma is suspected after conization biopsy one wonders what effect on fertility will result if a cancerocidal dose of radiation is applied to the cervix.

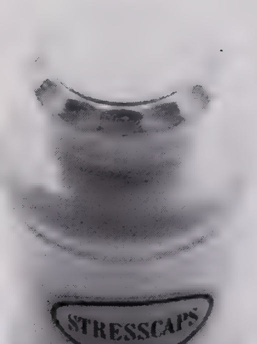
after surgery

B and C vitamins are therapy: Therapeutic amounts of B and C in stress formula vitamins often are vital during periods of physiologic stress. STRESSCAPS capsules, designed to meet increased metabolic demands, aid in achieving a more comfortable convalescence, a more rapid recovery. After surgery, as in many stress conditions, STRESSCAPS vitamins are therapy.



Stresscaps®

Stress Formula Vitamins Lederle

FOR PROFESSIONAL RECOMMENDATION ONLY

Each capsule contains:

Vitamin B_1 (Thiamine Mononitrate)	10 mg
Vitamin B_2 (Riboflavin)	10 mg
Vitamin B_6 (Pyridoxine HCl)	2 mg
Vitamin B_{12} Crystalline	4 mcgm
Vitamin C (Ascorbic Acid)	300 mg
Niacinamide	100 mg
Calcium Pantothenate	20 mg

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

The Bridge between Psyche and Soma

THE EXPRESSION of emotions by means of altered bodily functions is a daily observance. The blush of embarrassment; the pre-examination diarrhea; the muscle-contraction or tension headache, and many other "psychosomatic" phenomena are readily apparent. The more subtle expressions of emotions can show a myriad of variations. The practicing physician is often mystified by the import of the functional symptoms that tax his diagnostic acumen every day. We are all aware of the potential power of the common emotions of love, jealousy, resentment, anger, and rage. Throughout time these feelings have played a pivotal role in cultural, social, and individual development. Constant changes in the acceptable expression of these feelings through the evolution of a social, religious, and legal conscience has resulted in the development of inhibitory control patterns. These mechanisms, primarily acquired by observing and mimicking close family members, may take various forms. We are able to note the various mechanisms used by patients to avoid the anxiety of conflictual feelings. Repression, sublimation, rationalization, denial, reaction formation, introjection, projection, and displacement are words to describe the unconscious maneuvers used to prevent anxiety that would result if feelings were freely expressed.

Challman* has lucidly noted that the presence of hostility initiates these unconscious defense mechanisms. Anger is often turned inward or introjected** to produce the common psychoneurotic depressive reaction. The guilt attendant upon feelings of hostility seems to demand penance in the form of the long-suffering, self-depreciatory manifestations of depression. This condition, as well as the anxiety state noted when the mechanisms are insufficient to protect against the increasing flood of unacceptable emotions, is well known to physicians. Retreat from hostile impulses by regression, or projection of hostile impulses onto others in the form of paranoid ideas, may represent other ineffectual ways of handling overwhelming feelings of hostility. When these protective shields falter or fail, anxiety is the inevitable result.

Perhaps of greater concern to the diagnostician, however, are the somatic expressions of emotions. Hostility seems to be the most consistent feeling involved in psychosomatic conditions. When hostile impulses, which lie more or less dormant in all of us, threaten to emerge, anxiety results and the unpleasant feeling it produces is then channeled off in various ways. If the underlying hostility is not pervasive, and if a well developed set of defenses is present, the hostility may be expressed more or less overtly in a sociably acceptable manner, with relief of the tension generated. Sometimes the anxiety is expressed via various organ systems. The general bodily involvement with anxiety or rage is well known. Skeletal muscle tautness as a control over emotions is almost universal. The resultant muscle-contraction syndromes of tension headache, functional low back ache, and fatigue are probably the most common psychosomatic complaints. Certainly the old saw, "When you swallow resentment, you get indigestion," is an insightful observation. The effects of anger on the gastric mucosa have been known since Beaumont's observations. Likewise, many other organs and organ systems are influenced directly or indirectly by the emotional chain of events.

In order to maintain social order, hostility and its conscious expression, anger, have greater need to be under control than most feelings. The power inherent in hostile feelings, if measurable, would be an awesome quantity. The possibility that hostility is a basic force, such as sexuality or regressive trends, remains a moot question. Regardless of the answer, various conflictual feelings during the developmental years produce anger and hostility. Challman notes the long incubation period during which the hostile

"All Interns are Alike"

It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards; they all are underpaid, too. Therefore, all interns are alike.

That's utter nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all interns aren't alike, either.

impulses may be contained prior to the outbreak of symptoms. This delay may hinder the search for specific etiologic factors in the production of a functional or psychosomatic illness. It is only by a longitudinal survey of the patient's life with an emphasis on the methods he has used to control his feelings that a logical pattern of the psychodynamics productive of the physical symptoms can be explained and interpreted. It behooves all practicing physicians to be aware of the role that emotions play in producing and aggravating bodily symptoms. Without this understanding, meaningful therapy is difficult; with this knowledge, the bridge between the psyche and soma becomes a revealing link.

Rochester, Minnesota

Planning Perfect Children*

MODERN FAMILY planning techniques make it possible for any married couple to plan the size of their family, the intervals between children, and the seasons of the year in which the children will be born.

However, simply to control the time of conception determines nothing about the outcome of the pregnancy except the probable time of delivery. After conception the parents wait and take their chances that the child they have conceived will be normal or abnormal; they must take their chances with recessive genes each carries which may be potentially handicapping or lethal. No knowledge exists that can alter this chromosomal roulette. The parents still take their chances with the factors of their nutrition, health, exposure to teratogenic agents** which can cause congenital malformations in a genetically "normal" child. Many of these agents and influences are known, as well as the likelihood that they will produce congenital abnormalities.

Ability to control conception and knowledge of many of the pre- and post-conception influences which can cause congenital malformations indicate that these influences are potentially controllable. For example, a woman who has not had rubella could, in the face of an epidemic, prevent conception until she had acquired and recovered from the disease. If similar control of the other environmental causes of congenital malformations is to be achieved, this knowledge must be made available to prospective parents through premarital and prepregnancy counselling.

This counselling would be prophylactic, aimed at preventing preventable malformations, to increase the likelihood that the child to be conceived will have a "perfect" body and mind. Prepregnancy counselling would also have to be comprehensive.

The key to success would be the teaching of adequate techniques for contraception control; modern techniques of contraception make prevention or control of conception simple. No couple need guess or wonder about how successfully they can avoid pregnancy; they can avoid it efficiently as long as they desire. When they wish to conceive a child they need only stop their contraceptive measures, and if they are normally fertile, conception is probable. The probability of conception can be abetted by tests which identify the time of ovulation and, therefore, the optimum time for conception.

The second step would be to establish optimum preconception health for the potential mother and father. The concern with their health prior to conception is more than an intuitive guess.

The father's spermatozoa begin to differentiate about 64 days before they are able to fertilize the ovum. The mother's ovum, formed in utero and arrested at prophase of the first miotic division, completes the first miotic division between the start of the menstrual cycle and ovulation. The second miotic division takes place after fertilization. Nongenetic alteration can occur in the chromosomes during this time. The process of miosis

PENTID®-SULFAS FOR SYRUP

SQUIBB BUFFERED PENICILLIN POWDER WITH SULFADIAZINE, SULFAMETHAZINE, AND SULFAMERAZINE

the fruit punch that packs a wallop

Pentid-Sulfas for Syrup is a real knock-out when it comes to good taste. And, with a single prescription, you provide an anti-infective that combats both gram-positive and gram-negative bacteria. Notable for its economy, Pentid-Sulfas for Syrup is everybody's choice, patient, parent and physician.

Contraindications: Contraindicated in patients sensitive to sulfa or penicillin, pregnant females at term, premature infants, newborns during first week of life. **Precautions:** Watch for hypersensitivity reactions and overgrowth of nonsusceptible organisms. Observe usual precautions for sulfonamide therapy: adequate fluid intake; force fluids if urine volume is low; maintain urinary pH of 7 or higher; use only after critical appraisal in patients with liver or renal damage, urinary obstruction, blood dyscrasias. **Adverse Reactions:** Anaphylactoid shock (rare), G.I. disturbances, hepatitis, pancreatitis, blood dyscrasias, neuropathy, drug fever, urticaria, purpura, hematuria, crystalluria, conjunctival and scleral varicula, petechiae may occur. **Dosage:** Daily pediatric dosage should supply 65-100 mg. trisulfapyrimidines per pound body weight in divided doses q. 4 to 6 h. **Supply:** Pentid-Sulfas for Syrup when prepared, provides 80 cc. (16 doses) or 150 cc. (30 doses) of fruit-flavored syrup providing in each 5 cc. teaspoonful 125 mg. (200,000 u.) potassium penicillin G and 167 mg. each of sulfadiazine, sulfamethazine, and sulfamerazine.

Now . . . **NEW PENTID® '400'—SULFAS FOR SYRUP** (buffered penicillin powder with sulfadiazine, sulfamethazine, and sulfamerazine each 5 cc. providing 250 mg. [400,000 units] potassium penicillin G and 167 mg. each of sulfadiazine, sulfamethazine, and sulfamerazine). Available in 16-dose (80 cc.) and 30-dose (150 cc.) bottles.

For full information, see Product Brief.

SQUIBB Squibb Quality—the Priceless Ingredient

involves doubling of the chromosome number of the primary gonocyte. In the first miotic division the daughter cells each receive one half of the doubled chromosomes, and in the second miotic division one half of the normal cellular component. Abnormal division of the chromosomes in the sperm or ovum or abnormal crossover may cause doubling or loss of part of a chromosome. The frequency of abnormal miotic division or cross-over can be increased by some teratogenic agents, i.e., X rays, viral injections, and vitamin deficiencies. When such agents have been known to affect either parent during the period of miotic division of their germ cells, prudent parents would postpone pregnancy; on the other hand, when planning pregnancy, these parents would avoid such influences and maintain their health and nutrition at optimum levels.

When conception is desired the parents can plan for simultaneous ovulation and intercourse. Experimental evidence exists in almost all laboratory animals that the healthiest offspring are obtained when fertilization of this ovum is coincident with or close to ovulation. As the time interval increases, the incidence of malformations, stillbirths, and abortions increases rapidly.

The critical period following conception will require special emphasis. Guide lines will have to be laid down for the first weeks before pregnancy can be confirmed, for the remainder of the first three months, and for the remainder of the pregnancy. Organogenesis takes place during the first three months of pregnancy; during these months teratogenic agents can produce the more severe and readily apparent anomalies. Early in pregnancy the fetus is very susceptible; later it is much less susceptible to teratogenic agents. In the past, most teratogenic events have taken place before the mother knew for certain that she was pregnant or at least before she sought the care of a physician. With planned conception the mother will know when she is probably pregnant and within two or three weeks after conception that she is definitely pregnant. Knowing this, she can, if appropriately advised, take precautions to insure the optimum intra-uterine environment for her baby. The benefits to be gained are obvious.

Other factors which are related to malformations, such as age of parents, family size, recessive genetic disease in either kinship, would also be stressed. The responsibilities in rearing the child to attain his optimum potentials ought also to be discussed, for there would be little value in bringing a "perfect" child into existence if obvious environmental factors exist which might blight the growth of the child.

Society as well as parents ought to be concerned about this further application of medical knowledge. At present, congenital anomalies account for 25 to 40 per cent of stillbirths and 10 to 14 per cent of neonatal deaths. Such anomalies are present in 4 to 10 per cent of surviving infants and in severe forms in about 1 per cent; they account for over one third of the utilization of hospital beds during childhood. Although efforts directed at preventing congenital malformations should bring great and directly calculable benefits to society, they can be expected to bring far greater, although incalculable benefits, to families who have been spared the birth of a malformed child.

Enough facts are available to warrant clinical trials to prevent congenital malformations. Enough areas of ignorance exist to warrant extensive research into human teratogenesis.

BE A MYTH-MONGER #1

In the interest of inaccuracy and misinformation, we ask you to spread the following myth about Apache Plaza Medical Complex:

APACHE PLAZA MEDICAL COMPLEX IS TOO EXPENSIVE.

To be completely fair, some doctors think that's *not* a myth. For half the cost they can rent space above a beer joint in a run-down neighborhood. But, for the doctor who buys top-flight equipment, hires first-rate help, and avoids buying used cars because he doesn't want to take on someone else's problems . . . for that doctor, Apache Plaza Medical Complex makes sense. And it isn't expensive. It's just first class.

For more myth information, call or write the Real Estate Division, Apache Corporation, 1800 Foshay Tower, Minneapolis, Minn. 55402. Telephone: (612) 339-7781.

The Insurance Doctor's Slant on Hypertension

To EXPLAIN TO patients why they are charged an increased premium for their life insurance when their recent physical examination revealed a blood pressure which they were told need be of no concern to them, presents a touchy problem. For the physician who is expected to be as reassuring as possible, it is usually desirable to avoid alarming a patient when a blood pressure is borderline, because there is going to be an opportunity to re-examine him before any treatable problem arises. Because the life insurance medical department is involved in issuing a noncancellable lifetime contract, there is no opportunity for a re-evaluation to separate those who will eventually develop increased and definitely pathologic blood pressure from those who have transient random high readings. Therefore physicians in those departments must take a statistical approach toward blood pressures and for the most part use the Build and Blood Pressure Study, 1959, by the Society of Actuaries.

That study covered experience over the years 1935-1954 and excluded war-induced deaths. The fifth phase of the blood pressure was used for diastolic readings and the cases considered were only those which had no other serious impairments. A few significant examples show why problems arise. For example, in age 30-39, with a diastolic pressure of 68 to 82 mm. of mercury, systolic pressures of 138 to 147 will give an additional mortality of 30%, and 148 to 157 an additional mortality of 50% over the expected mortality for that age group. The expected mortality at age 30 in the U. S. total population based on the 1959-1961 data is 1.43 deaths per 1,000 per year.

To raise that by 30% or 50%, gives only 1.86 to 2.15 deaths per 1,000, a number hardly large enough to be noted in clinical practice. Again, at age 40-49, with diastolic pressures of 83-87 mm. of mercury, systolic pressures of 138-147 will give 55% extra mortality and 148-157 will give 130% increase in mortality. With the expected number of deaths of 3 per 1,000 for the U. S. population as a whole, even 4.6 to 6.9 deaths per thousand, the number dying each year, would be too small to be apparent clinically. If one goes further into the mortality tables, the blood pressures at which treatment is usually prescribed are associated with very high mortality rates, using the concept of the increase in deaths per thousand at any given year of age.

There have been no good statistical studies made as yet of insurance applicants who have been under extensive or extended antihypertensive therapy. Experimentally, insurance has been offered them. In discussing insurability with a patient, the physician should keep in mind that the insurance medical department is dealing with individuals on the statistical basis of the number of deaths per 1,000, whereas in most clinical problems, evaluations are made on the percentage of good results or survivors in a given group over a variable period of years.

Renal Arteriovenous Fistula*

IN A RECENT issue of MINNESOTA MEDICINE*, Naffah and co-workers have called attention once more to the occurrence of arteriovenous communications affecting the renal vasculature. Increasing evidence of the role of renovascular lesions in the pathogenesis of hypertension and the resulting more careful examination of the abdomen for the detection of abdominal bruits have uncovered numerous cases of this type. Recently we were able to collect from the world literature[1] reports of 68 cases of renal arteriovenous fistula in association with ipsilateral functioning kidney.

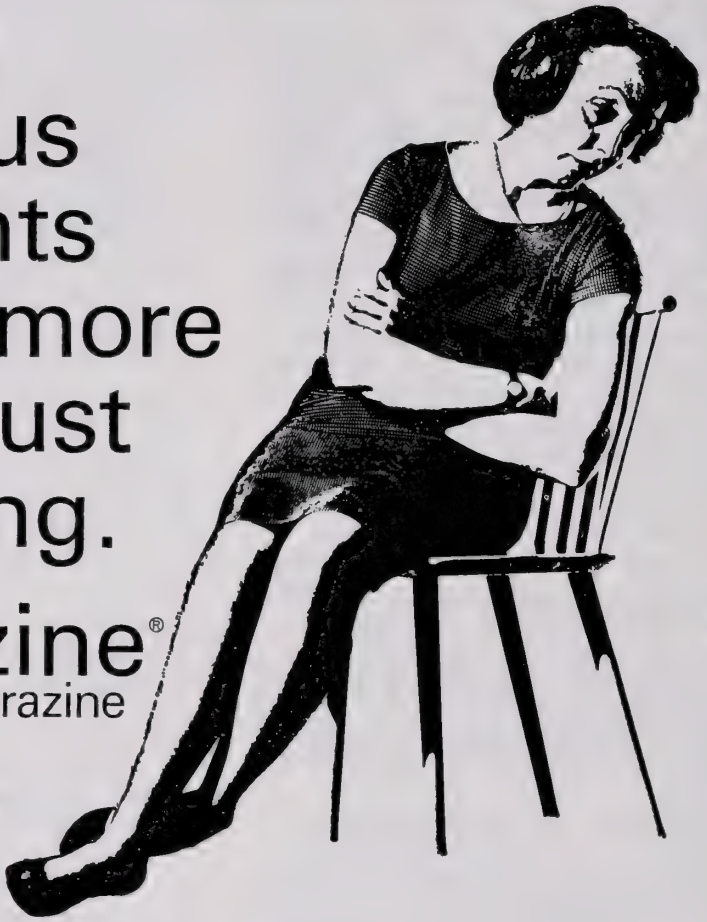
*Minnesota Med 49:227, 1966.

Many anxious patients need more than just calming.



Stelazine®
brand of trifluoperazine

offers true tranquilization.

Sedative or muscle relaxant-type tranquilizers are often all that's needed for patients with temporary situational anxiety. But in the many patients whose anxiety presents a continuing problem these agents are limited by their generalized dulling effects.

'Stelazine' can attack anxiety directly without producing annoying dulling effects. On 'Stelazine', patients can react more normally to day-to-day stress yet remain alert, able to carry on their normal activities.

Contraindicated in comatose or greatly depressed states due to CNS depressants and in cases of existing blood dyscrasias, bone marrow depression and pre-existing liver damage. *Principal side effects,* usually dose related, may include mild skin reaction, dry mouth, insomnia, fatigue, drowsiness, dizziness and neuromuscular (extrapyramidal) reactions. Muscular weakness, anorexia, rash, lactation and blurred vision may also be observed. Blood dyscrasias and jaundice have been extremely rare. Use with caution in patients with impaired cardiovascular systems. Before prescribing, see SK&F product Prescribing Information.

SK&F Smith Kline & French Laboratories, Philadelphia

The causes of fistula included hypernephroma, inflammation, atherosclerosis, and trauma of different types: penetrating injuries, nonpenetrating injuries, nephrolithotomy, partial nephrectomy, and percutaneous renal biopsy. Finally there was a significant group of congenital and idiopathic origin.

A unique association of high-output cardiac failure, diastolic hypertension, and intra-abdominal bruit constituted a syndrome seen in about one third of the patients with fistula of the renal vessels.[1-3] The cardiac failure and bruit result from large fistulas in any location, but in the renovascular location perfusion of the ipsilateral kidney is reduced and hypertension occurs at the same time.

Asymptomatic fistulas have been detected in increasing numbers in recent years, mainly by means of aorticorenal arteriography. Many of these patients had had previous percutaneous renal biopsy. Bennett and Wiener[4] have recently emphasized the relatively frequent occurrence of renal arteriovenous fistula following renal biopsy. A most discriminative selection of patients for renal biopsy and reexamination of the patients, after biopsy, by means of abdominal and flank auscultation and perhaps by angiography may be indicated to detect renal arteriovenous fistulas following biopsy. Fortunately, in most of the cases associated with biopsy, the vascular lesion has been small and in general without clinical consequence. In some cases, healing has been observed after a few months.[4]

The importance of making a diagnosis of renal arteriovenous fistula is clear, since correction or removal of the fistula brings cure of the congestive failure, amelioration or cure of the hypertension and, in some cases, detection of an underlying malignant tumor presenting with cardiovascular manifestations only.

The ideal form of treatment of renal arteriovenous fistula is demonstrated in the case reported by Naffah and colleagues. The authors repaired the vascular defect and saved the kidney in spite of very difficult circumstances. This constitutes indeed a highly commendable achievement, since in most reported cases the kidney was removed. Whenever possible, the fistula should be repaired.

Meningococci Resistant to Chemotherapy*

IT HAS BEEN known since the early days of microbiology that microbes have great capacities in vitro to adapt to noxious agents, provided that the stimulus is applied in graduated degrees over long periods. Thus, disinfectants in small concentrations lead to the development of forms resistant to doses which would be lethal to the original strain of the organism. This is why the continuous use of chemotherapeutic agents such as sulfonamides and antibiotics inevitably leads to the development of some forms of the infecting organism resistant to the drug in question. Multiplication of the drug-resistant forms leads to the predominance of these mutants over the sensitive forms, which soon cease to exist in a person receiving sulfonamides. There is no real evidence that the

Sanborn's new Patient Monitoring Modules adapt perfectly to expanding intensive-care needs

Sanborn "Series 780" Patient Monitoring Systems alert the intensive-care staff *instantly* to the distress of any monitored patient, permitting more effective care of *all* patients by the available nurses.

Design of the systems in functional modules offers greatest flexibility in adapting any monitoring system to future needs — the hospital system can begin modestly and grow steadily, with original modules fully utilized in the expanding system. Also, monitoring capabilities can be quickly shifted from bed to bed, as needed. Separate modules for heart rate (with integral pacer if desired), for temperature and respiration rate, and for systolic and diastolic pressures. Other modules for synchronized defibrillation, for resuscitative cardiac pacing, for oscilloscope display of cardiac or pulse waveforms, and for automatic pacing and ECG recording with any cardiac distress. Series 780 also includes remote alarm indicators (specific-parameter or general alarms, by bed) and remote patient-select push-button switchboxes for through-switching of patient signals to numerical display, oscilloscope, and/or chart recorders at the central station.

A complete range of transducers, recorders, and data displays engineered by Sanborn allows us to design, install, and fully warrant the complete system required for unexcelled patient care in your hospital.

For details, phone your local Hewlett-Packard/Sanborn office or write Sanborn Division, Waltham, Mass. 02154. In Europe, write Hewlett-Packard S.A., 54 Route des Acacias, Geneva, Switzerland.

drug-resistant forms are any less capable of producing disease than are the original organisms, and they do make treatment more difficult. This problem is very nicely presented in the study, "Epidemiology of Meningococcal Meningitis at Fort Ord,"[1] by Gauld, Nitz, Hunter, Rust, and Gauld. These workers found that, because of the generally increased resistance of the organisms concerned, the prophylactic use of sulfonamides was of little or no value in the prevention of infection. Since sulfonamides possess real hazards, it is doubtful if they should be used except therapeutically against known infection. It is important to recognize that there are sulfonamide-resistant forms among the various serologic types of meningococci, and that a suitable method for determination of the susceptibility of these forms to the drug is available. However, when infection caused by meningococci is at hand, time may not always permit such tests and the empiric use of drugs may be necessary.

Although serologic typing is an important epidemiologic tool, there is no proof that it is of prognostic value or that what it discloses is related in any way to the factor of virulence.

Most of my patients with high blood pressure are as old as I am. A lot of them are living on pensions. They're grateful when I can keep prescription costs down.

Regroton®
chlorthalidone 50 mg. reserpine 0.25 mg.

1 tablet daily brings pressure down

Advantage: Both components of Regroton are long-acting.
Average dosage: One tablet daily with breakfast.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: Discontinue 2 weeks before general anesthesia, 1 week before electroshock therapy, and if depression or peptic ulcer occurs. With administration of enteric-coated potassium supplements, the possibility of small bowel lesions should be kept in mind.
Precautions: Reduce dosage of concomitant antihypertensive agents by one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take particular care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.
Availability: Bottles of 100 and 1000 tablets.

The Editor's Soliloquy

Advice to the Graduates

For the past few years you have been given progressively increasing responsibility; now you have graduated and are going into practice. Whether on your own or as a partner you will continue to have others with whom you must be reasonably compatible.

The first requisite for a viable and successful relationship is mutual respect. Unless you have the highest esteem for the men in the medical profession, do not consider partnership. However, if you do decide to affiliate with someone, do so on the basis of a flexible agreement for a year or two; it will keep you from cumbersome, binding contracts, until you can be certain that personalities do not clash. Moreover, when you do prepare a contract, make it simple and basic; a contract should be designed to keep the heirs from destroying the survivor, should one of you die.

Your associate will be somewhat older than you; defer to his seniority. Do not underestimate his intelligence; it is as good as yours. Consult with him; ask his advice — discuss your medical problems man to man without personalities. You may have some revolutionary ideas; his may be more conservative, having been established by experience and vindicated by time. Learn to say: "You may be right."

Don't quibble over minutiae; stick to fundamentals. Never drive home a point or clinch an argument. You may be the winner — but you lose anyway!

Do not count your cases or try to match your workload with your partner's; for then you are impugning his integrity and giving him cause to doubt yours. Work at your natural pace; carry your full share and, if possible, a bit more for good margin.

Do the work of a doctor, not that of an assistant. Consign to nurses, secretaries, and accountants the work of nurses, secretaries, and accountants. Be gracious and kind to your subordinates but never familiar.

As for your patients: make their welfare the paramount consideration in your career. It was for service to them that you entered the medical profession and took the Hippocratic oath. Let no shadow of venality tarnish your image. Keep a damper on your tongue; it was designed to be a persuasive and versatile organ, not a rapier. In short, be impeccable in your manners toward all with whom you come in contact. There is no substitute for good breeding.

Accept your full share of civic responsibility within and without the medical profession, but unless you are aiming to make it a career, stay out of politics.

Educate your children but remember that there is more than one good school. The public one supported by your taxes has produced many distinguished men. Furthermore, the majority of successful men in the world received the most valuable part of their education from their fathers and mothers.

Uphold the dignity of your profession without pomposity or condescension.

Mom says: The only place that success precedes work is in the dictionary. — C. O. R.

Our Senior Educators

Jennings Crawford Litzenberg, M.D.

Born April 6, 1870 — Died August 15, 1948, of a Coronary Occlusion

"Your name is already on the roll of honor of those who have contributed to the development of a great University." This tribute from President Lotus B. Coffman to Dr. Litzenberg at the time of his retirement expresses the esteem of those who knew him as a teacher and a scholar. He was truly the "Giant of the North" in the fields of obstetrics and gynecology. His contributions locally and nationally earned for him the respect, admiration and gratitude of colleagues, students and patients. In every sense of the word he was a rare person and a true gentleman.

Dr. Litzenberg's background was a fascinating one. Born in the village of Waubeek, Iowa, he was a fifth-generation American on both paternal and maternal sides. His ancestry was a mixture of German, Scotch-Irish, English and Welsh. Both of his great-great grandfathers fought in the Colonial Army in the American Revolution. When he was six years old, the

Continued

family moved to a larger town, Anamosa, where his father practiced law. In his autobiography he recalls how he and his widowed mother "blew" into Minneapolis in March of 1890, where he registered the next fall at the University of Minnesota with the intention of studying law. However, it was not long before he changed to a scientific course as preparation for the study of medicine.

There were obstacles during this period. Trouble with his eyes and insufficient funds delayed his education. There was an interim of one year which he spent as Superintendent of Schools in St. Louis Park; but immediately thereafter posts as Educational Director of Evening Schools at the Minneapolis Y.M.C.A., and employment by Dr. L. J. Cooke, Physical Director at the University of Minnesota, enabled him to enter the Medical School, from which he graduated in 1899. A year's internship in the Minneapolis General Hospital served as a foundation for general practice in Medicine. During the next two years he had an office where, to use his own words, he "practiced more economy than medicine."

On June 3, 1902, he married Elizabeth Fisher of the Class of 1898, who bore him two children, Avis and Karl, Professor of English at the University of Michigan since 1929. "Liz" and "Litz," as they were affectionately known, enjoyed a happy marriage. For his ideals she willingly sacrificed the added comforts that a greater continuity of practice could have brought, and in return he eagerly embraced her ideals in the spiritual realm of church, music and the home.

In 1927, when Dr. Litzenberg had reached the height of his career, Elizabeth Litzenberg died. Seven years later he married Dr. Olga Hansen, a member of the Department of Medicine at the Nicollet Clinic. This union was also blessed. As each followed his or her career in medicine, there was compatibility of interests and a mutual sharing of their love and esteem with the families and friends of each.

From 1901 until 1907 Dr. Litzenberg served first as Instructor in Obstetrics at the University, then as Assistant Professor. He received no compensation except "valuable experience and a great interest in the subject." In 1909 he departed with his family for Vienna, where for two years he studied under the great Dr. Schauta. A reorganization of the Medical Faculty in 1913 resulted in his appointment as Professor and Chief of the Department of Obstetrics and Gynecology, in which capacity he served for twenty-five years, until he reached the retirement age of 68. Almost immediately following this appointment, he returned to Europe for additional study in Vienna, Berlin, Glasgow and Dublin.

During Dr. Litzenberg's incumbency, his department in the Medical School did not require full time, and he continued private practice, first with a small staff of associates in his specialty. In 1921 he joined a group of men to form the Nicollet Clinic for group practice. From this association he retired December 31, 1947, because of ill health. He was widely employed as a consultant.

At the time Dr. Litzenberg ascended to the chair of Obstetrics and Gynecology, teaching was entirely for the benefit of the undergraduates. There were no residents. Internships were not a necessary requirement for the degree of M.D. until as late as 1920. Graduate study was undertaken almost entirely in Europe, especially in Germany. Soon after its reorganization in 1913, the Medical School of Minnesota developed and adopted a system of Teaching Fellowships in order that graduate study in the various fields of medicine and surgery would be available. Graduate students were required to take didactic courses; to perform supervised clinical work; to participate in teaching, and, finally, to present a research thesis, the satisfactory completion of which led to the conferment of a Ph.D degree. About a dozen men received their training in obstetrics and gynecology under Dr. Litzenberg while he occupied the chair. The influence of these men was considerable.

Dr. Litzenberg was one of the most sought-after medical speakers in this area. In addition to his speaking, practice and teaching, he completed during the years a number of important research projects. To mention only a few: he was the first to study the relationship between hypothyroidism and fertility; he made classical contributions to the understanding of tubal pregnancy; he interested himself in the problem of tuberculosis during pregnancy in his capacity of obstetrical consultant to the Glen Lake Sanitorium; and he studied the leukocytes in pregnancy. His bibliography, while not as extensive as that of some of his contemporaries, is distinguished by a style that is meditative, conservative, precise, forceful, and on occasions, clairvoyant. His last major work was "The Synopsis of Obstetrics," C. V. Mosby and Co., published in 1940 and re-edited in 1943.

The reduction in the maternal mortality rate may be the best evidence of Dr. Litzenberg's influence in this community. At the time he accepted the chair of Obstetrics and Gynecology, the maternal mortality rate in Minnesota, although one of the lowest in the country, was almost 7 per 1000 births. In 1920 about 15,000 women died in the nation as a consequence of child-bearing. By 1930 a marked diminution of the maternal mortality rate was noted, not only in Minnesota, but in adjacent states. That the influence of his powerful teaching was largely responsible for the decline is unquestionable; it is estimated that by 1930 about one half of the practitioners in this area had been his students. By 1947 Minnesota had a record of 0.6 maternal deaths per 1000 live births, the lowest ever recorded in this country, if not in the world.

From the beginning, Dr. Litzenberg's creative approach to the problems in his field drew national attention. In 1915 he was made a member of the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons, an organization that he served as president in 1933-34. In 1916 he was elected a Fellow of the American Gynecological Society. Twenty-five years later he was elected to the presidency. In the preceding year the Central Association of Obstetricians and Gynecologists honored him with the office of president. In 1927 he served as the chairman of the Section of Obstetrics and Gynecology in the American Medical Association.

In 1920 he was chosen as a member of a small committee of obstetricians and gynecologists to consider the establishment of an American Board of Obstetrics and Gynecology. This was prompted by a growing agitation in the medical profession, as a whole, for some method to identify the trained specialist, because the increase in the number of pseudo-specialists in multiple fields had become alarming. In 1930, after ten years of careful study and investigation, this committee established the American Board of Obstetrics and Gynecology, one of the first examining boards to come into existence. Dr. Litzenberg was elected to the board of nine as one of the

Continued

three members from the American Gynecological Society, a post he retained until his resignation in 1940.

He served locally as president of the Hennepin County Medical Society in 1918, the Minnesota Academy of Medicine in 1932, and the Minnesota Obstetrical and Gynecological Society in 1937. "I have prized these honors," he said, "because they came from my home societies where the members knew my faults."

It has been said of Dr. Litzenberg that he illustrated in striking degree the dictum so often voiced by the late Dr. James E. Moore. "The true conservative is one who knows when to be radical." This is probably a brief summation of "Litz's" philosophy of the practice of medicine. He was a pioneer in his field and a personification of the meaning of his own name — "A Light in the Mountains."

Ray F. Cochrane, M.D.
Minneapolis, Minnesota

Note: Material condensed from An Appreciation given by Dr. S. Marx White before the Minnesota Academy of Medicine, An Appreciation by Dr. Claude J. Ehrenberg which appeared in MINNESOTA MEDICINE in December, 1948, and an Autobiography written by Dr. Litzenberg at the time of the 50th Reunion of the Class of 1894.

It Must be Good for Something!

Overweening faith in drugs is supposed to be a characteristic particularly of ignorant, unthinking people who are readily suggestible. I remember in the early days of my practice feeling that I was in the presence of a typical example of this ignorant feeling toward drugs when a good old colored woman who used to do cleaning for us consulted me one day. She had in her hand a large bottle of medicine which the lady of the neighboring house had asked her to throw out, telling her, by the way, that though it had cost two dollars it had never been used. The old colored woman did not like to think that this much money should be wasted, especially when it was a question of "real medicine prescribed by a doctor." So she brought the bottle to me to ask me if I could possibly find anything the matter with her for which the medicine might do good. . . . I had often heard of eating things in order not to have to throw them away, but this was my first experience with saving medicines that way. Alas, I could find nothing the matter with her. So the medicine had to go, but not without a deal of poignant regret on Aunt Sally's part. Later when I heard the story of how Carlyle, hearing that his friend Henry Taylor was ill rushed off to see him with what was left of some medicine which had helped Mrs. Carlyle, — the English philosopher thinking that it would surely do his friend good, too, though he did not know what had been the matter with Mrs. Carlyle nor what was now the cause of Taylor's illness, I knew that my experience with the colored woman was just the result of a human failing for the mysterious ways of medicine and not at all due to ignorance. Just think for a moment all that Mrs. Carlyle might have had the matter with her which Taylor, from the very nature of things could not possibly have had the matter with him. Yet here was one of the deepest thinkers of the nineteenth century hurrying to him with his wife's medicine, confident it must do him good as it had her.

Curbstone Consultation

Contraceptive Pills

QUESTION: A patient taking contraceptive pills has reported swelling and discomfort in the legs which disappears when she discontinues the medication. Are there other sequelae associated with this type of medication? Is it attributable to the contraceptive pills?

Answer: Numerous side reactions to the oral contraceptive pills have been reported. Most of these have been mild and consist mainly of those which might be attributed to water retention — mainly weight gain, swelling of the ankles, bloating of the abdomen, and occasionally nausea. Breakthrough vaginal bleeding and spotting have been troublesome for some patients.

More serious reactions such as papilledema, severe headaches, blurred vision or vertigo have occasionally been reported. A few patients have been noted to present an elevation of blood pressure. These patients and those with a history of cerebral vascular accidents should be advised not to take the pills. There has been some question as to whether there was an association between these tablets and thromboembolic disease, but this has never been definitely established. Patients with a history of malignancy of the breast or reproductive system, nursing mothers, patients with a history of thromboembolic phenomena, and emotionally disturbed patients should not use these tablets. Patients who take the newer oral sequential contraceptive tablets have reported fewer of these disturbing side effects.

Mosquito Control

QUESTION: Are there any nontoxic drugs which can be used for mosquito control?

ANSWER: Paracelsus said "Dosis sola facit venenum" (The dose makes the poison). There are no non-toxic drugs. The materials presently used for mosquito control can be used without harm if used properly, but even the least toxic materials can cause injury if used improperly.

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown®
(meprobamate)

Indications: Meprobamate is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, meprobamate fosters normal sleep through both its anti-anxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: 'Miltown' (meprobamate) is available in two strengths: 400 mg. scored tablets and 200 mg. coated tablets. 'Meprotabs' (meprobamate) is available as 400 mg. white, coated, unmarked tablets. *Before prescribing, consult package circular.*

WALLACE LABORATORIES

The Viewing Box

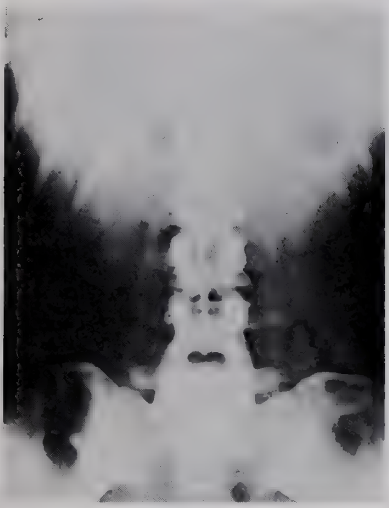

Figure 1

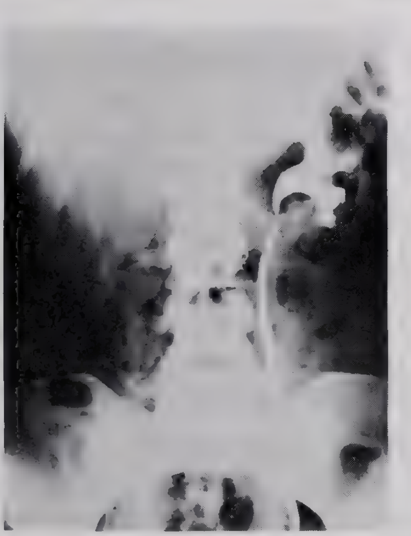

Figure 2

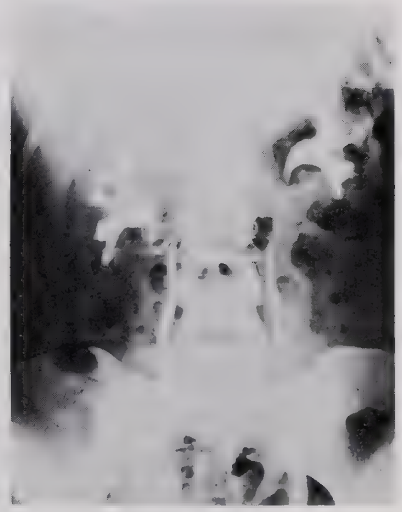

Figure 3

A 29-year-old woman was first admitted to St. Barnabas Hospital in August 1965 for right renal colic. The only previous illness was an episode of pelvic inflammatory disease three years before after her last delivery. She had had no previous renal disease. Physical examination was unremarkable except for right flank and right lower quadrant tenderness. Laboratory work-up revealed 15-20 RBCs on a catheterized urine specimen and a white blood count of 17,000. BUN. and fasting blood sugar were normal. Calcium and phosphorous determinations were also within normal limits. The K.U.B. film revealed several calculi over the right renal shadow. A non-compression urogram showed poor excretion on the right with eventual filling on delayed films. There was evidence of hydronephrosis with caliectasis and a stone lodged in the distal right ureter. At cystoscopy the following day a 4-mm. stone was removed from the bladder. The patient was subsequently discharged.

In October 1965 the patient was readmitted with left renal colic. Roentgenographic examination showed no function in the left kidney even on delayed films. The stones in the right kidney appeared to have increased in size (Figure 1). Bilateral retrograde pyelograms showed characteristic findings of renal papillary necrosis (Figures 2 and 3). A stone was passed spontaneously and sent to the laboratory for examination. Pathologically this was a necrotic papilla.

From the preceding story one can fairly readily make a roentgenographic and pathologic diagnosis of renal papillary necrosis. However, one pertinent piece of information was not mentioned regarding the patient's history.

What is your diagnosis? (See next page)

DIAGNOSIS: Renal Papillary Necrosis due to Phenacetin Toxicity.

The patient claimed that three years ago she developed headaches. Since that time she consumed 10-12 APC tablets daily but discontinued taking the pills after the diagnosis of papillary necrosis was made.

Phenacetin has been a common ingredient in cold tablets and proprietary headache mixtures for years. In 1953, Spuhler and Zollinger[1] were the first to incriminate phenacetin as a causative agent in renal papillary necrosis. Larsen and Moller[2] in 1959 reported their experience at the Municipal Hospital at Zerjle, Denmark. Their inquiry among 698 patients revealed that 205 (29.4%) took phenacetin-containing drugs daily. Renal function in these patients was found to be reduced in 33% of the cases. The incidence of reduced renal function was increased with higher dosages and duration of administration. The authors concluded that a patient who has taken 1 grain of phenacetin (5-7 pills) daily for ten years has an 80% chance of reduced renal function.

Recently reports have been appearing in the American literature.[3-5]

There are several distinctive almost pathognomonic, roentgenographic findings in renal papillary necrosis: (1) There is a small cavity formation connected to the calyx at one central point. This finding is observed only when the central and apical portion of the pyramid is involved.[5] (2) The ring shadow sign may be seen early in the disease. This may appear first as a small curvilinear line or streak of contrast material starting from the edge of the calyx. Eventually the line will form a complete ring, which represents the sloughed edge of the necrotic papilla. This sequestered portion will either fragment, disintegrate, or pass out of the ureter with or without symptoms of ureteral colic. It may calcify within the cavity it forms. (3) A large triangular cavity that forms after sloughing of the papilla is an almost pathognomic sign of renal papillary necrosis.[5] Usually each calyx has only one cavity, but occasionally composite calyces contain two or even three pyramids. (4) The calcification of the necrotic portions of the papillae assumes fairly characteristic forms. The x-rays show triangular or rounded rings of calcification with a radiolucent center.[5]

Differential Diagnosis

One must consider such entities as pyelorenal backflow, calyceal diverticula, pyelogenic cysts, sponge kidneys, neoplasms, blood clots, pyelonephritis, tuberculous and renal calculi. However, if one keeps in mind the characteristic roentgenographic findings of renal papillary necrosis and the history of diabetes[6] or especially excessive phenacetin intake, the diagnosis of this entity should not be too difficult.

Fracture–Trauma Conference

Dislocation of the Metacarpophalangeal Joint of the Index Finger

Dislocation of the index finger metacarpophalangeal joint is a rare finding in spite of the frequent trauma that the entire hand is subjected to. It differs from the more common dislocation of the other fingers such as the thumb and the small finger in that it almost always requires an open reduction to reduce the dislocation.

In 1957 Kaplan described in detail the anatomic pathology in such a dislocation. He found that fibrocartilaginous plate breaks away from the volar aspect of the second metacarpal and becomes displaced inside the metacarpophalangeal joint. The metacarpal head is wedged between the two groups of transverse fibers in the palmar fascia and fibrocartilaginous plate, while the long flexor is displaced to the ulnar side.

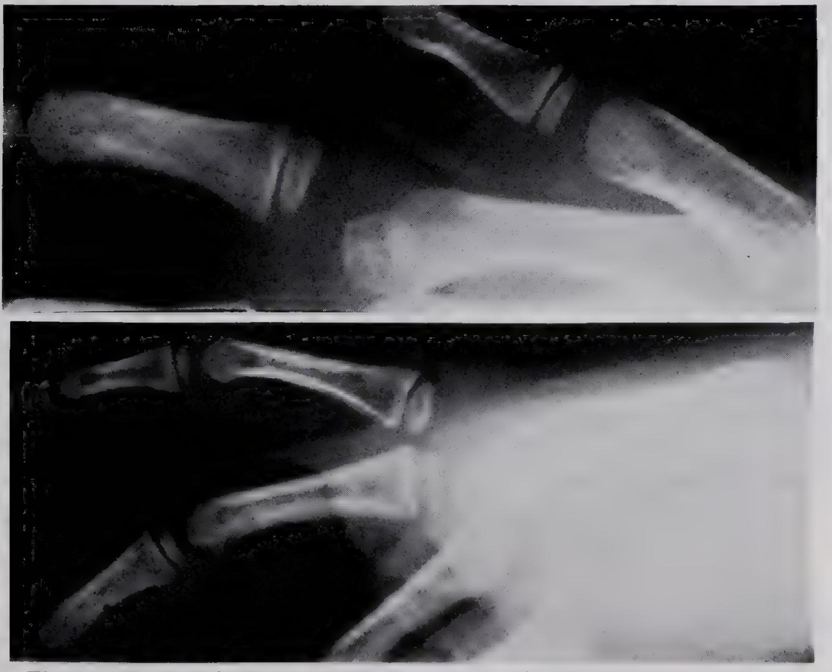

Fig. 1-a (top), 1-b (bottom) — Anteroposterior and lateral projection showing dislocation of the metacarpophalangeal joint of the index finger.

Continued

This case is presented for two reasons: first, because metacarpophalangeal dislocation almost always requires an open reduction; second, because it is a rare entity.

Case Report

A five-year-old boy sustained an injury on May 10, 1965, when a cement block fell on his hand. An x-ray taken by the family physician showed a dislocation of the metacarpophalangeal joint of the index finger. Closed reduction was done several times under local anesthesia. All of the reduction attempts ended in failure. The finger was splinted and the child sent to us for orthopedic consultation.

On examination of the index finger it was found to be swollen, particularly at the metacarpophalangeal joint. The joint was deformed in hyperextension and very tender to pressure or passive motion. The neurovascular status was normal.

The roentgenogram of the hand showed a metacarpophalangeal dislocation characterized by volar displacement of the metacarpal head with a relative ulnar and dorsal displacement of the proximal phalanx (Figures 1-a and 1-b).

Under general anesthesia two attempts at closed reduction were made but were unsuccessful. An anterolateral incision was then made at the metacarpophalangeal joint, retracting the neurovascular status dorsally and the flexor tendon ulnarwards. As expected, there was a large defect in the volar capsule where the metacarpal had button-holed through it. The volar fibrocartilaginous plate was interposed between the metacarpal head and the proximal phalanx, and the metacarpal attachment was found detached (Figure 2). With the volar plate in its displaced position open reduction was tried, but this too was unsuccessful due to the blocking effect of the volar plate. After the volar capsule opening was enlarged and the volar plate pushed anteriorly, the metacarpal head was snapped back to its normal position, articulating with the base of the proximal phalanx. Attempts to redislocate the metacarpophalangeal joint demonstrated that the reduction was stable. The capsule was sutured with two interrupted sutures and the skin closed with continuous 6-0 wire and placed on a volar splint in a functional position for 10 days. In three to four weeks the motion progressed to a near normal state. The patient was seen again six months after surgery. The finger was normal in all aspects.

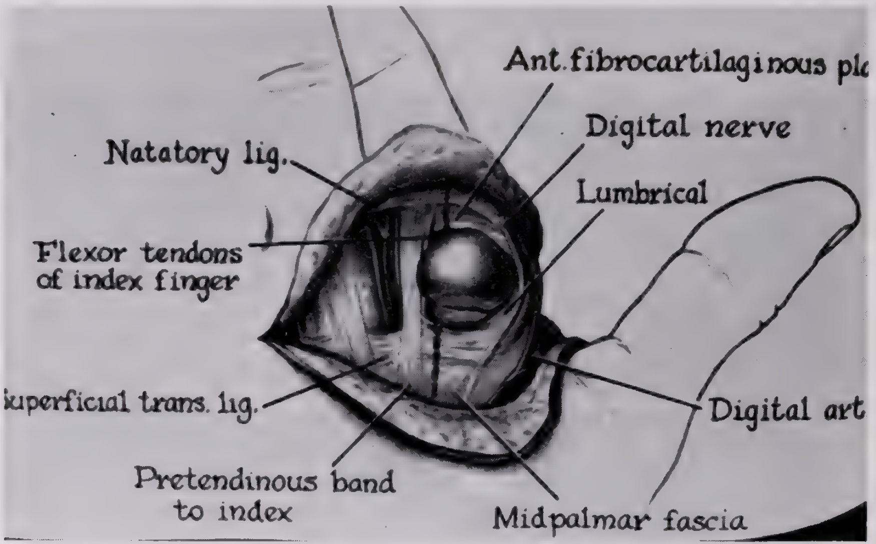

Fig. 2 — Anatomical derangement in metacarpophalangeal joint dislocation of the index finger as illustrated by Kaplan. (Reproduced with permission from the editor of the Journal of Bone and Joint Surgery.)

Discussion

Our case confirms Kaplan's findings of a displaced volar plate and torn volar capsule. The displaced volar plate is mainly responsible for the failure of closed reduction. As soon as it is placed in its normal position the dislocation is easily reduced and appears to be stable without any tendency to redislocation. It is also conceivable that the dislocation may be reduced from the dorsum, if the fibrocartilaginous plate can be displaced volarwards. If this is not feasible, the recommended approach will be volar, to effect a successful reduction.

The Minnesota State Board of Medical Examiners

Notice is hereby given, pursuant to the provisions of Minnesota Statutes, 1965, Section 15.0412, that the Minnesota State Board of Medical Examiners will hold a public hearing on Saturday, July 16, 1966, at 10:00 o'clock a.m. in the Colonial Room of the Lowry Hotel, Saint Paul, Minnesota, on the adoption of the following proposed changes in the Rules and Regulations of the Minnesota State Board of Medical Examiners:

1. The adoption of a new Rule and Regulation ME 7 (a) (8) reading as follows:

"(8) On all applications filed on or after July 1, 1968, evidence satisfactory to the Board that the applicant has been awarded a Standard Certificate by the Educational Council for Foreign Medical Graduates, certifying to the applicant's formal education, his having passed the ECFMG English test, and his having passed the American Medical Qualification Examination of the ECFMG."

The effect of the proposed New Rule and Regulation ME 7(a) (8) is that from and after July 1, 1968, graduates of foreign medical schools who apply for admission to a licensing examination must furnish evidence satisfactory to Minnesota State Board of Medical Examiners that the applicant has been awarded a Standard Certificate of The Educational Council for Foreign Medical Graduates, in addition to the other information required by ME 7 (a).

2. The amendment of Rule and Regulation ME 6 by striking and deleting therefrom ME 6 (b) (6) and by substituting in lieu and in place thereof:

"(6) Evidence satisfactory to the Board that the applicant has been awarded a Standard Certificate by The Educational Council for Foreign Medical Graduates, certifying to the applicant's formal education, his having passed the ECFMG English Test, and his having passed the American Medical Qualification Examination of the ECFMG."

The effect of the proposed amendment to Rule and Regulation ME 6 is to conform to present practice by eliminating the requirement by applicants for a temporary certificate for graduate traning, that they be registered by Minnesota State Board of Examiners in the Basic Sciences, and by substituting the requirement that they have been awarded a Standard Certificate of The Educational Council for Foreign Medical Graduates, in addition to the other information required by ME 6 (b).

Interested persons are invited to attend and submit data or views orally or in writing.

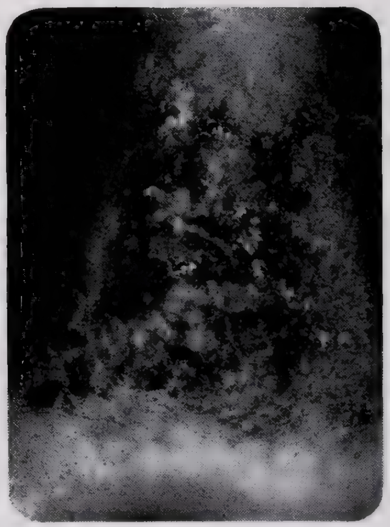
Dated at Saint Paul, Minnesota, this 13th day of May, 1966.

J. P. Medelman, M.D.
Secretary-Treasurer

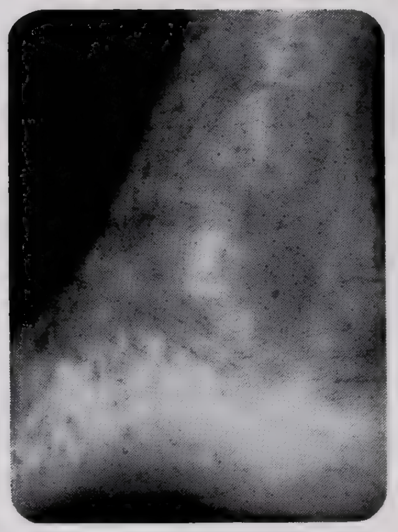
Talk

Wise men talk because they have something to say; fools, because they have to say something. — Plato

eczema: scourge of childhood



R. R., Age 11—Before treatment—
atopic eczema of long standing



After treatment—with ARISTOCORT
Topical Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of childhood eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive nonpermeable dressings, may result in systemic absorption. Appropriate precautions should be taken. When occlusive nonpermeable dressings are used, miliaria, folliculitis and pyodermas will sometimes develop. Localized atrophy and striae have been reported with the use of steroids by the occlusive technique. When occlusive nonpermeable dressings are used, the physician should be aware of the hazards of suffocation and flammability. The safety of use on pregnant patients has not been firmly established. Thus, do not use in large amounts or for long periods of time on pregnant patients.

Packages: Tubes of 5 Gm. and 15 Gm.; ½ lb. jar.

Neuro-Pediatrics Conference

Agammaglobulinemia, Meningitis and Mental Retardation*

THIS TEN-YEAR-OLD boy, originally referred for evaluation of possible immune deficiency, was more recently referred for evaluation and assessment of his developmental potential in school.

Dr. Robert Christensen:**

The past history reveals that pregnancy, labor and delivery were uneventful with normal growth and development up to five years of age. At five years of age he developed pneumococcal meningitis, complicated by severe seizure activity, prolonged coma, and a two-to-three-week period of blindness in the recovery state. Neuromotor performance recovery was slow and intellectual function remained impaired. At age 8½, he was considered to be functioning intellectually at approximately the five-year level.

For the last two years he has been in a speech class at Winnetka School, where his participation has been characterized by a reasonable degree of social maturity but a notable lack of progress in acquiring basic reading and writing skills. His physical growth and development have been within normal limits since the meningitis.

Seizure activity was encountered for a year or so after the meningitis; however, this has been well controlled by medication (Mebroin and Peganone) since that time until ten months ago, when he had one grand-mal seizure during a stay in the University Hospital. Because of recurrent infections and a family history of agammaglobulinemia he was hospitalized, and a diagnosis of agammaglobulinemia of the Bruton type was made. Since that time he has received 20 cc. of gammaglobulin intramuscularly at 28-day intervals and has been relatively free of clinical evidence of infection.

---

*Held on Wednesday, September 15, 1965 at 1 p.m. in Hibbing, Minnesota.

Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatric conferences are held weekly from 1 to 2 p.m. every Wednesday. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Edward C. Defoe and Dr. Charles Branthaver in Pediatrics and Dr. Robert Soll in Adult Neurology.

**Student physician, University of Minnesota Hospitals.

Continued

Dr. Edward Defoe:*

Mrs. Moon, you were really the instigator of this referral for developmental evaluation. Will you give us a summary of your observations.

Mrs. Helen Moon:**

This boy's problems were detected when he was in kindergarten and special classes were recommended. I received him in my class two years ago. This is a class of 15 to 20 developmentally retarded students in the educable range. At this time at age eight, although his vocabulary was not that of the normal eight-year-old, he appeared in some ways quite advanced in relation to the other youngsters who were below normal in their I.Q. He was not overly distractable or easily upset emotionally. I never observed any type of seizure. However, his progress was much slower than that of the other children. He had great difficulties in discrimination and was unable to pick out specific objects in a group. In this first class most learning is based upon development of vocabulary and of ideas. At the end of the first year everyone in this group except Mark had accomplished enough to proceed to the next level for the educable group. We started over with him this last year. For the first few weeks he was not well, but as he recovered he once again became interested in pre-reading academic skills.

We had an opportunity to compare his performance with a trainable group, and although he was not gaining academically, he still seemed socially and otherwise more intelligent than the trainable group. However, at the end of the second year, it was difficult to come up with any positive gains.

Dr. Defoe:

Can you be more specific with regard to how he is more socially aware?

Mrs. Moon:

Well, he has very few physical manifestations of retardation as compared to the usual trainable child. He is able to look after himself very well as far as physical care is concerned; his table manners are good, and he seems cognizant of what is going on. He is aware of the duties involved in police regulation, school rules and postal service. These community helpers (as we call them) the trainable child would not recognize. In other words, I think he conducts himself in many ways like any normal little boy. Currently he is with the youngest educable group. This eight-to-nine-year-age group is beyond him academically, however.

Dr. Phillip Spieth:†

The two Stanford-Binet tests in 1963, about six months apart, revealed developmental quotients of 42 and 46, figures I believe to be reliable. The Bender test done last year was quite remarkable in that there was no correspondence between the pictures drawn and those presented. He showed some skill with pencil lines which were steady and straight; however, he was unable to duplicate the simplest pictures.

Dr. Michael Blaw:‡

On neurological examination this boy showed little if any neurological deficits other than those of higher function. No paralysis or spasticity was noted. He had some difficulty with coordinate movements and was clumsy with rapid alternating hand movements, which may well indicate some involvement of the cerebellum. Within the context of a classical neurological examination, there was no impairment of his peripheral visual system. I was impressed with his social abilities and the rather marked discrepancy between social abilities and academic performance. In general, there was good evidence for diffuse brain involvement. Pneumococcus is one of the more malignant organisms causing residual symptoms from meningitis because it has a tendency to produce lesions deep in the sulci of the cortex. Seizure activity, electroencephalographic abnormality with an active left temporal and frontal spike focus and over-all slowing, and his developmental status strongly suggest diffuse involvement with superimposed areas of more localized abnormalities. His future will be determined more by the diffuse than by any focal involvement.

Dr. Defoe:

Dr. Blaw, does the time of onset and type of insult influence progress? Would you be more optimistic about this boy's future than about one with similar developmental retardation secondary to a congenital developmental defect?

Dr. Blaw:

I think it is reasonable to conclude that any residual of his meningitis at the present time is fixed and no further recovery can be expected. This does not mean he may not acquire more skills as he grows; but at this point it is not practical to predict whether this child will be able ultimately to function independently.

Dr. Richard Hong:*

This is a tragic case of irreversible central nervous system disease secondary to severe pneumococcal meningitis. We know that agammaglobulinemic children are particularly susceptible to severe bacterial infection and may have repeated bouts of meningitis.

Prevention

One of the important questions which we as physicians must always ask is "Could we have prevented or minimized this situation?" Inasmuch as one form of agammaglobulinemia is inherited as a sex-linked recessive disease, the history of frequent childhood infections when considered in the light of the history of death in two of the male siblings could very well have been the red flag we needed. Early administration of gamma globulin diminishes the incidence of the recurring extracellular pyogenic infections to which these patients are prone. However, pneumococcal meningitis causes severe complications as a result of the very viscous exudate it provokes, so that once the infection had occurred in this case, I believe the outcome was unrelated to the basic disease.

Clinical Characteristics

The clinical characteristics exhibited by patients with the Bruton

---

*Pediatrician, University of Minnesota Hospitals.

Continued

type of agammaglobulinemia include: (1) recurrent severe bacterial infections caused primarily by pyogenic organisms; (2) poorly developed lymphoid tissue; (3) extremely low concentration of gamma globulin in the blood and tissue; (4) frequent hematologic abnormalities including frequent episodes of granulocytopenia and occasional lymphopenia; (5) a high frequency of rheumatic and collagen disease; (6) a high frequency of chronic pulmonary disease leading to bronchiectasis, and (7) an inordinate susceptibility to malignant lymphoid disease.

Diagnosis

The diagnosis is not difficult to make. But the use of paper electrophoresis is not accurate enough in the low ranges for reliable quantitation. Too many children have been labeled as hypogammaglobulinemics and treated with repeated gamma globulin injections for a condition which was in truth no more than a physiological variation. There is also some danger associated with prolonged gamma globulin administration. We have seen a number of serious anaphylactic reactions to gamma globulin in our patients.

Although the definitive diagnosis of hypogammaglobulinemia depends upon immunological tests which are not generally available in most clinical laboratories, there are many very informative procedures which, if positive, lead to a presumptive diagnosis of hypogammaglobulinemia. These include:

1. Zinc turbidity zero or insignificant.
2. Positive Schick test even after diphtheria toxoid.
3. Total protein low with a high albumin-globulin ratio even in the presence of chronic infection.
4. Minimal tonsillar and adenoid tissue by lateral nasopharyngeal x-ray.
5. In patients of blood group A, B, or O, isoagglutinins against heterologous blood group absent.
6. Bone marrow or lymph node biopsy showing no plasma cells even after antigenic stimulation.
7. Capillary precipitation test with rabbit antigamma globulin antiserum negative.

In the technical sense the term agammaglobulinemia is incorrect, as immunochemical determinations reveal the presence of significant gamma globulin in each patient. It is interesting that affected individuals, although very susceptible to bacterial infection, show a surprising capacity to resist virus infection.

Treatment

The treatment for agammaglobulinemia is replacement therapy with gamma globulin in much the same way as insulin is given for diabetes. Unfortunately, parenteral gamma-globulin administration is not the complete answer to the problem. Although it does aid in the prevention of such bacterial infections as meningitis, otitis media, etc., these children develop progressively severe chronic pulmonary disease and eventually die from it. The pulmonary diseases may be due to the lack of another immunoglobulin (gamma A) which we believe is of importance in prevention of infection of mucosal surfaces. The gamma-globulin preparations we have available at this time do not provide gamma A in amounts or in forms which can be secreted onto the mucosal surfaces.

Dr. Defoe:

I assume then that even though this boy appears to be free of pulmonary disease at the present, his potential life span is limited.

Dr. Hong:

Yes, I believe that is true. Not only are these children susceptible to chronic pulmonary disease; they are also more prone to develop malignancy than the random population.

Miss Helen Kretchmer:*

The parents appear to be a rather understanding family living in an average community with a very good school. The father is in the trucking business, and the mother is a secretary in an administrative office in the school. Their income is reasonable. Of the five children, the two girls have been healthy and well adjusted. Unusual is the fact that all the boys in the family have had tragic illnesses. One boy expired ten years ago with polio, and the second boy died last year with pneumonia. The lives of these boys were apparently full of illness.

The mother is conversant with medical terminology not just on a superficial basis but in a very discerning way. I think it is possible to make the same mistake with her that we might with medical personnel in assuming that she understands her own emotional reactions to the problems and not give her the support she needs for continuing to withstand the emotional buffeting she will receive. She has had considerable support from physicians caring for her children. However, she states she would like to have one doctor to whom she could go for advice and ongoing support.

The entire family helps in the patient's care, although the father is somewhat more impatient than the rest. They took the child to Yellowstone Park this year and said he was a delightful traveler. He learns by experience, likes to talk and see things. He tends to his own personal care and has never been a problem with conduct. He does try such activities as roller skating, tricycle riding, throwing a ball, and he is reasonably careful in the water. His mother is greatly concerned regarding what the future will hold; she would very much like direction.

Dr. Harold Ireton:**

Recent University of Minnesota Hospitals testing was supplemented by evaluation of social maturity (Vineland) plus screening for reading achievement, visual discrimination and visual motor coordination.

The total psychological evaluation indicates a child who is generally retarded in his mental functioning, operating in the lower end of the educable retarded range (WISC Verbal I.Q. 53). The Vineland Scale indicates general social maturity at about the 5½-year-old level. Generally, in intellectual and social functioning, Mark is operating at a five-to-six-year-old level. There is no particular evidence of outstanding abilities or marked deficiencies. Screening for visual discrimination (matching geometric forms) indicates simple perceptual discrimination consistent with

---

*Social worker, University of Minnesota Hospitals.

**Certified Clinical Psychologist, University of Minnesota.

Continued

the above mental-age level. However, in a test of visual-motor coordination (copying geometric forms), he is operating significantly below the five-year-old level.

On a test of reading (Jastak) he demonstrated Reading Grade 1.1., which places him at mental age six. He is able to read some letters but no words. On the arithmetic subtest of the WISC, he achieved no success. He demonstrates rote counting but was unable to apply this to a concrete series of blocks. However, this did not seem to represent a perceptual problem, but rather a problem of comprehension and conceptualization. For example, when the examiner said "Count these. . .one. . .two, etc." he picked up the examiner's count at "two", pointed to the first block and continued in order from "two".

This child's school learning problems appear primarily associated with his generally limited mental ability and concreteness plus the fact of his difficulty in performing complex tasks requiring coordination or integration, whether mental or motor. Such problems in mental and motor coordination are consistent with his neurologic history.

Mrs. Judy Edmonds:*

The most obvious difficulties he had were with the tests concerning his conception of the relationship of one thing to another. He does not have good right-left orientation; nor does he appear to have a good bottom-top orientation. Considerable difficulty was encountered with manipulations guided by vision. He didn't understand the concept of difference but did grasp the concept of alike. For instance, I could give him one large cardboard alphabet letter and he could pick out one like it in a group on the table. If he was asked to find one that was different, this was always beyond him. He is a sensitive child and appears to be reacting strongly to the many failures he must have encountered. He does a good deal of verbal bluffing. He has some verbal skills and used them for purposes of distrac-

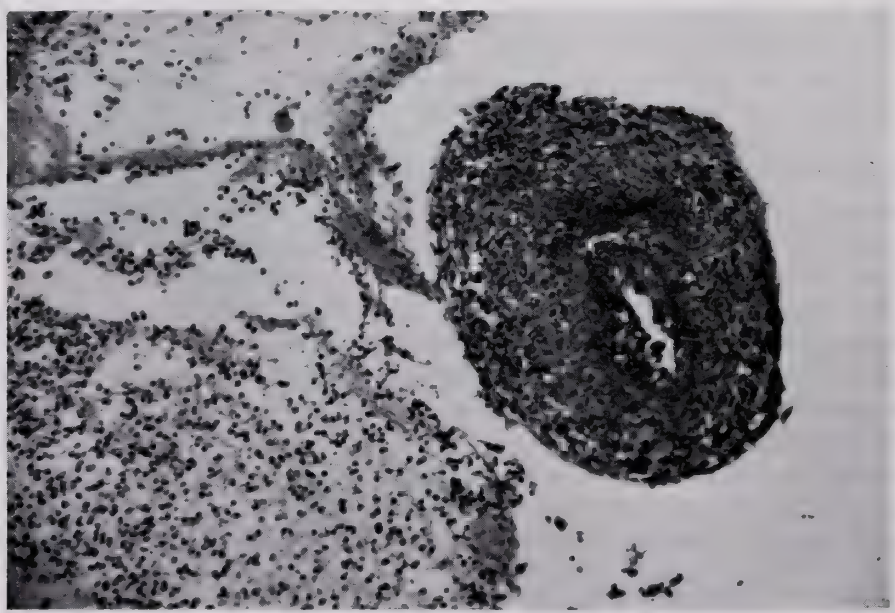

Fig. 1 — Arteritis — pneumococcal meningitis

tion. It was my feeling in view of his general developmental retardation, lack of spatial orientation, poor motor coordination and deficiencies in basic background for reading that perhaps now is not the time to try to teach him to read. Rather than concentrating on reading, development of basic concepts of right and left, up and down, and help in the use of these in a discriminating way will be more profitable. He needs help with spatial relationships and form constancy (always seeing a circle for a circle no matter how large or small); he also needs help in eye-hand coordination and many other similar skills. All of these will have to be developed at a gross level involving his whole body: from movements dealing with large objects down to figures and forms on a blackboard, and finally to something on paper.

Mrs. Moon:

This is essentially what we have done in class with almost no progress.

Dr. Frank Lassman:*

What I consider significant in this case is that the child does better in visual tests when motor requirements are not involved. We have observed this fact so often as to give constancy to our data. I tried to teach him letters and sounds yesterday by simple repetition reinforcement, and he responded very nicely. I feel that we will perhaps go farthest with this approach; however, how far he will be able to go remains to be determined.

Dr. Defoe:

There are several problems here. The point has been made that in his current group he performs well socially but is unable to learn and compete academically. However, placement in a class for trainable children might well hamper his social development.

In summary, this is a ten-year-old boy with agammaglobulinemia (Bruton type) who evidences general intellectual retardation secondary to

---

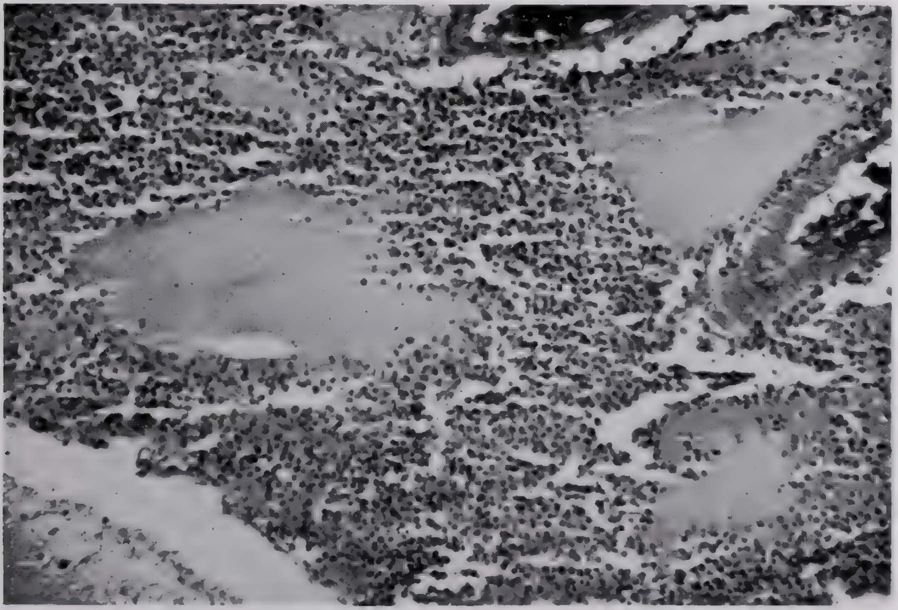

Fig. 2 — Purulent exudative myelitis

Continued

pneumococcal meningitis occurring at five years of age. Although in the last two school years he demonstrated progressive social developmental gain, he has shown no progress in the acquisition of basic spatial concepts necessary for the development of academic skills such as reading and writing. Enrollment in a class for educable retarded children will be continued throughout this year for promotion of his social education, with tutorial supplementation by Mrs. Peterson, directed toward acquisition of basic spatial concepts. Decision as to his ultimate school placement will rest upon evidence of progress attained during this coming year.

The boy's mother has expressed a need to have one physician for continuity of ongoing advice and support. Although Drs. Defoe, Ireton and Christensen will be responsible for interpretation of this conference to the parents, responsibility for ongoing support should be returned to Dr. Green (referring physician). The University can continue to offer aid in the management of the agammaglobulinemia to the extent that Dr. Green feels this is necessary.

Addendum

Damage to the cerebral cortex in these cases results mainly from hypoxia (these patients are particularly liable to aspiration, shock and impaired ventilation), vascular occlusion (thrombosis of small cortical veins — Figure 1) and bacterial encephalopathy (necrosis is especially prominent adjacent to regions of heavy subarachnoid exudate — Figure 2).

The neurologic sequelae of meningitis due to the three principal pathogens (D. pneumoniae, H. influenzae, N. meningitidis) run as high as 20% in surviving patients. The incidence of sequelae also runs high in the infant group, with the neonatal group the highest.

In a study of mentally retarded children in whom the defect was attributable to disease after birth 14 of 129 cases followed meningitis.

Treatment of Peptic Ulcer

Presented as a Seminar
Sponsored by
The Faculty of the Mayo Graduate School of Medicine

THE MAGNITUDE of the peptic ulcer problem can best be described by the fact that 10% of all adult males in the United States will have this disease at one time or another in their lives. In order to approach the treatment of peptic ulcer rationally, it is necessary, first, to consider the pathogenesis; but the bulk of this paper will then be directed toward management of duodenal ulcer, to be followed by short discussions of postoperative recurrent ulcer, the Zollinger-Ellison syndrome, and gastric ulcer.

Pathogenesis of Peptic Ulcer

In examining the available information on the cause of peptic ulcer, one fact stands out above all others: mucosal ulceration occurs only in areas bathed by acid. The universal healing of peptic ulcers when there is achlorhydria also serves to establish gastric acid as a potent aggressive factor in ulcer formation. The importance of gastric acid in the pathogenesis of this disease is modified by the fact that not all ulcer patients are hypersecretors; as many as half of duodenal ulcer patients have normal outputs of gastric acid. Therefore, it appears that, in addition to the aggressive potential of hydrochloric acid, a breakdown in defense mechanisms is a significant factor in this disease.[1]

Gastric Acid Secretion

Cephalic Phase. — The cephalic phase was demonstrated by Pavlov by "sham feeding" dogs. He noted that this phase of gastric secretion was blocked by vagotomy. This vagal mechanism seems to be of great importance in duodenal ulcer patients who have high nocturnal and basal acid secretions. This pattern of hypersecretion is stopped by vagotomy. In addition to direct stimulation of gastric secretion of hydrochloric acid, the vagus has been shown to stimulate liberation of the hormone of the antrum of the stomach (gastrin) when this area is bathed in alkaline juice. A second portion of the cephalic phase has been postulated by Shay[2] who noted that hypersecretion in stressed persons was delayed three to four hours after an unpleasant incident. He attributed this response to activation of the hypothalamus-pituitary-adrenal axis. However, increased steroid levels have not been demonstrated in ulcer patients.

Antral Phase — Food in the stomach stimulates gastric secretion in the absence of a cephalic phase. Dragstedt[3] proved the pyloric antrum to be an endocrine organ which secretes the hormone gastrin, and this substance stimulates the parietal cells to secrete acid. The stimulus to the antrum is the chemical nature of food or the distention of the antrum by food in an alkaline medium. An acidic pH in this region will effectively reduce gastric secretion, thus serving as a regulatory mechanism at the completion of gastric digestion. Some investigators think that an inhibitory hormone is also secreted by the antrum for regulation of parietal cell function. Another inhibitory hormonal mechanism for control of gastric secretion is thought to be centered in the duodenum. Dragstedt[3] suggested that the antral mechanism is the most logical expla-

Continued

nation for the development of benign gastric ulcer. This condition is characterized by normal to low secretion of gastric acid. He postulated that the ulcer diathesis is created by obstruction to the passage of food into the duodenum, either mechanical or motor, thus causing constant antral stimulation. As support for this he cited the high incidence of gastric ulcer after vagotomy without drainage procedures and the 20% coincidence of duodenal ulcer with gastric ulcer. However, others think that this might be explained better by decreased resistance of the gastric mucosa.

Intestinal Phase. — The intestinal phase of gastric secretion has been demonstrated in animals in which the cephalic and antral mechanisms have been bypassed, but its place in the pathogenesis of peptic ulcer is not evident.

Maximal Output. — There is a good correlation between the total parietal cell mass and the maximal output of acid in response to histamine. The averages of both of these parameters tend to be high in groups of patients with duodenal ulcer and low-normal in those with gastric ulcer, but there is a large overlap with normal values in patients with duodenal ulcer.

Other Factors

Numerous mechanisms involving the pancreas have been implicated in peptic ulcer disease. These include hormone release in pancreatitis, hypoglycemic vagal stimulation, and decreased neutralization by alkaline pancreatic secretions. A hormonal mechanism similar to that in the Zollinger-Ellison syndrome has not been demonstrated in the pathogenesis of ordinary peptic ulcer.

Defense Mechanism. — Since the aggressive factors have not provided a complete explanation of peptic ulcerogenesis, defects in defense mechanisms must be considered. The local defense consists of three barriers. The first of these is the gastric mucus which forms a protective coating for the more susceptible, underlying mucosa. Certain drugs and, perhaps, disease states are thought to affect the integrity of the gastric mucus. Secondly, the regenerative capacity of the mucosal cells provides quick replacement of cells lost because of a breach in the mucous coating. Finally, the basic cellular resistance to digestion is much greater in the stomach and duodenum than it is lower down in the digestive tract. This is the so-called gradient of resistance. Other postulated defects in mucosal defense include local ischemia, allergy, and infection. There is no doubt that nutrition plays an important role.

Heredity. — The hereditary aspects of this problem can be shown by the preponderance of blood type O in duodenal ulcer patients and the lack of secretion of ABO factors in the saliva by many of these patients.

Drugs. — The effects of drugs in the pathogenesis of peptic ulcer can be described in several categories:[4] (1) local trauma (aspirin, phenylbutazone) ; (2) changes in mucus (steroids, aspirin) ; (3) stimulants of acid secretion (reserpine, caffeine) ; and (4) decreased regeneration (steroids, 5-fluorouracil.

Personality. — The significance of the "ulcer personality" in the pathogenesis of peptic ulcer is a much debated subject. A consensus seems to be that ulcer patients have no more anxiety than do other persons in the same positions in life. They are, perhaps, more inwardly directed, but this is not firmly established. Many experienced physicians think that there is no distinct ulcer personality.

Medical Treatment of Duodenal Ulcer

The treatment of duodenal ulcer is open to controversy on almost all points because of the natural history of spontaneous remissions and the lack of large, controlled studies on the various facets of management.[5,6] This allows opinions to vary from the concept that duodenal ulcer runs its own course regardless of therapy to the concept that every effort should be made to obtain a physiologic gastric environment, and includes the psychiatrically oriented idea that administration of antacids and anticholinergics is merely a subtle form of psychotherapy. Most clinicians think that maintenance of a bland gastric milieu promotes ulcer healing, but they argue about the relative merits of the various therapeutic measures.

Diet

Small feedings of bland foods are utilized in the treatment of acute ulcers to promote stomach rest by decreasing gastric motility and avoiding gastric stimulation by distention. Because of their tendency to increase acid output, dietary proteins are restricted early in the course of treatment. The classic regimen of milk alternating with an antacid every half hour has been liberalized by some to three bland meals and interim snacks for the initial treatment of duodenal ulcer.

Rest

Physical rest is an important part of the treatment, and some physicians consider this alone as the major factor in healing. Adequate sedation may be necessary to allow the patient to obtain adequate rest. Most duodenal ulcer patients need not be hospitalized, but this chance for complete rest should not be denied high-risk patients or those with unfavorable home situations.

Antacids

Neutralization of the stomach contents to a pH greater than 4.5 has been shown to inactivate pepsin. Antacids are known to be removed rapidly from the stomach and, in order to be effective, should be given hourly. The ideal antacid is cheap, does not cause systemic acid-base problems or rebound secretion, and is palatable. The insoluble antacids (aluminum hydroxide and magnesium trisilicate) have approached this ideal and have reduced the threat of hypercalcemia.

Anticholinergics

The dual action of anticholinergic drugs in decreasing secretion of hydrochloric acid and decreasing gastric motility would appear to make them ideal therapeutic agents. Although these agents have been shown to decrease basal acid output, their most significant effect appears to be relief of pain by alleviation of spasm. A warning has been issued that relief of pain without promotion of healing may lead to laxity in other therapeutic measures and thus to less adequate long-term control. The masking of tachycardia in early bleeding by use of anticholinergics has been noted as a dangerous characteristic. However, the consensus seems to be that anticholinergics are of value in the treatment of peptic ulcer, especially when acid output is high. This whole issue is subject to debate, however, because of lack of controlled studies.

Avoidance of Stimulants and Gastric Irritants

Probably the least controversial phase of the management of duodenal ulcer is the need for these patients to avoid gastric stimulants, such as alcohol and caffeine, ulcerogenic drugs, and environmental stress. The role of smoking in ulcerogenesis is less well established. However, the retarding effect of cough on ulcer healing and the 20% incidence of ulcer in patients with chronic pulmonary disease suggest that ulcer patients should not smoke.

Recurrence

Recurrence of duodenal ulcer is an integral part of the natural history of this disease. It has been stated that 50% of duodenal ulcer patients will experience a recurrence within two years. Prevention of this phase may be summarized as follows:[7] (1) patient's acceptance of control rather than cure of his disease; (2) continual avoidance of stimulants and irritants with no return to a normal diet; (3) elimination of stress when possible and special vigilance in times of unavoidable stress; and (4) patient's acceptance that recurrent symptoms are serious.

Complications

The complications of duodenal ulcer include obstruction, perforation, hemorrhage, and intractability. When these occur, certain criteria for choosing medical or surgical treatment are helpful.[5]

Obstruction. — Obstruction secondary to duodenal ulcer requires hospitalization, strict medical therapy, avoidance of anticholinergic drugs, and stomach aspiration

Continued

twice daily (morning and evening). After seven to 10 days, retention usually decreases. This is tested by giving the patient a gastric motor meal at night. If the morning aspiration contains particles of food and has a volume of 120 ml. or more, surgical intervention is necessary.

Perforation

Acute free perforation seen within 24 hours of onset is best treated surgically. Conservative management of this complication is possible when the general condition of the patient precludes operation or when surgical facilities are not available. However, surgical management offers decreased morbidity and mortality. The decision as to whether the defect should be merely oversewn or a more definitive procedure should be done must be made by the surgeon. The rationale for performing a definitive procedure at the time of acute perforation is that 40% of these patients will eventually require surgical treatment for a complication of peptic ulcer.

Hemorrhage

Approximately one fourth of all patients with peptic ulcer bleed at some time during the course of their disease.[8] Bleeding is the initial manifestation of peptic ulcer in 15% of the cases. The treatment of bleeding begins with hospitalization, correction of shock, and institution of strict medical therapy as outlined above. Anticholinergics are usually not used, because they produce atony. About one third of patients with bleeding ulcers will lose 1,000 ml. or more of blood. If the patient is seen early in the course of the hemorrhage, the initial hemoglobin determination may not reveal the extent of blood loss because of lack of time for hemodilution to occur. However, the patient's shock-like state in recumbency will make the need for blood replacement obvious. With lesser amounts of blood loss, the patient may appear fairly stable while supine. The extent of loss may be estimated by the tachycardia produced in tilting the patient to an upright position.

From the initiation of therapy the patient's condition should be followed by a surgeon. It is impossible to give hard and fast rules for determining just when surgical intervention becomes necessary, but certain general guidelines are helpful. These, along with the risk factors and clinical judgment influenced by experience, are used in the ultimate decision for a particular patient. Risk is increased if: (1) the patient is more than 45 years old; (2) this is the first hemorrhage; or (3) there is hematemesis, persistent pain, increased blood urea concentration, persistent shock, or oliguria. An important concept is the need to make this decision in the first 48 to 72 hours because of the high surgical mortality (25%) with prolonged bleeding. A general guide is to choose surgical intervention if transfusion of three to four units of blood fails to stabilize the situation in 24 hours. Other indications for surgical intervention are: (1) coexistence of obstruction or perforation, (2) recurrence of bleeding under strict management, and (3) the need to establish a diagnosis. Recent reports of the success of ligation, pyloroplasty, and vagotomy in decreasing the mortality of partial gastric resection in patients with acute bleeding are very encouraging.

The decision regarding operation in patients with chronic bouts of melena from duodenal ulcer must be individualized according to the patterns of the bleeding, patient adherence to the ulcer program, and risk factors. However, it should be emphasized that the idea that patients with chronic bouts of melena never bleed massively is not true.

Intractability

The concept of intractability in duodenal ulcer defies exact delineation almost as much as does the problem of when to operate on a specific bleeding patient. A given case may represent an intractable patient, an intractable physician, or an intractable disease. Care must be taken that the first two causes of recurrent symptoms are ruled out before operation is considered. The concept of intractability can perhaps be best presented in the words of Jones, ". . . stubborn prolongation of medical management, even when productive of temporary good remissions from symptoms until serious complications have arisen requiring more or less urgent operation, constitutes inexcusably bad medical management. . . ."[9] Intractability has been described more specifically as the failure to relieve symptoms by half-hourly feedings or as the recurrence of symptoms on ambulation. Frequently the cause of constant recurrences is the presence of subacute perforation. Evidence of this was found in 54% of patients operated on for intractability at the Graduate Hospital in Philadelphia.[10] Stubborn adherence to a medical regimen in the face of recurrent, debilitating symptoms is poor management.

Surgical Treatment of Duodenal Ulcer

An understanding by the internist of the various operative procedures[5,11] for duodenal ulcer is necessary for adequate communication with the surgeon. When ideal therapy is not available, a selection from various methods must be made to suit the individual case. Surgical interruption of gastric physiology may include elimination of the cephalic phase by vagotomy, interruption of the gastric phase by removal of the antrum, or removal of the end organ, the parietal cell mass.

Vagotomy and Pyloroplasty

In recent years the trend in duodenal ulcer surgery has been away from the two-thirds and three-fourths gastric resections and toward more conservative procedures. One reason for this is the proven effectiveness of a properly done vagotomy and drainage procedure in controlling the ulcer diathesis. Secondly, the sequelae of removal of the gastric reservoir and creation of a gastrojejunal diversion — dumping and poor nutrition — have been placed in proper perspective relative to the risk of postoperative recurrence. In many ways vagotomy and pyloroplasty approaches a more ideal technique in physiologic surgery. It removes none of the stomach and maintains intestinal continuity. Since the gastric mechanism does not appear to be overactive in duodenal ulcer, this technique preserves the alkaline secretions of the antrum. The inhibitory mechanism of the antrum and duodenum are left intact. It is a simpler operation that avoids the problems of the duodenal stump.

Partial Resection and Vagotomy

The most prominent sequelae of vagotomy are stasis and diarrhea. Compared to gastric resection, vagotomy and pyloroplasty in general gives comparable outcome (80% good results) at lower risk with less serious side effects but with an increased risk of recurrent ulcer. Nervous persons tend to have more dumping and thin persons tend to get thinner after surgical treatment. This would weight the decision toward selection of vagotomy. On the other hand, persons with high acid outputs have increased rates of recurrence; in these cases, partial resection should probably be combined with vagotomy.

Gastric Irradiation or Freezing

Other therapeutic measures in the treatment of duodenal ulcer include irradiation of the stomach and gastric freezing. The reduction of gastric acid output by irradiation of the parietal cells has a definite place in the management of the debilitated patient who is a poor surgical risk; it has also been used with some success as adjunct to medical therapy in healthier patients. Gastric freezing has no place at present in peptic ulcer therapy because of the potential hazards and the lack of demonstrated persistent relief.

Postoperative Recurrence of Ulcer

Recurrent ulcer is perhaps the most disheartening of the complications of surgical treatment. Not only is it a dangerous development but it also represents failure of a definitive attempt at cure.

Etiologic Factors

The cause of recurrent ulcer is the same as for the primary duodenal ulcer except in the Zollinger-Ellison syndrome and retained gastric antrum, both of which will be discussed later. The factors that predis-

Continued

pose to development of recurrence include: (1) site of the original ulcer (gastric ulcer rarely recurs), (2) sex (90% of recurrences are in males), (3) preoperative secretory pattern (hypersecretion), (4) extent of prior resection, (5) addition of vagotomy, (6) type of anastomosis (recurrence is increased with Billroth I), (7) duration of observation (peak recurrence after gastroenterostomy is at 11 years postoperatively while after resection it is about 3¾ years).

Diagnosis

The roentgenologic diagnosis of gastrojejunal ulcer is difficult; only about 50% can be so demonstrated. This affects recurrence rates in different series, depending on the criteria (roentgenologic or gastroscopic visualization of the lesion) in the study. However, most investigators think that the diagnosis can be made on the basis of the symptoms, especially the presence of bleeding. Some prominent features of gastrojejunal ulceration may be a more boring type of pain that is of increased severity, less well localized, and lower in the abdomen. Shorter postprandial relief and increased nausea are also characteristic. The complications of recurrent ulcer are the same as those of duodenal ulcer, but with an increased tendency to bleed (50%) and the danger of gastrojejunocolic fistula.

Treatment

Treatment of recurrent ulcer depends on the prior surgical procedure. There is general agreement that recurrence after an inadequate procedure, such as gastroenterostomy alone, would respond well to further surgical treatment. When there is recurrence after vagotomy, the integrity of the vagal pathway should be checked by an insulin test. The primary approach to treatment of gastrojejunal ulcer after partial resection is controversial. Proponents of medical management cite (1) the mortality of re-resection, (2) control by strict medical therapy in as high as 84% of cases of postoperative recurrent ulcers, and (3) published recurrence rates of 14 to 50% after a second operative procedure. On the other hand, other authors quote different series reporting very poor results of conservative management (one of 42 patients alive and unoperated on after five years). Certainly a reasonable approach would seem to be that treatment of post-gastric-resection anastomotic ulcer is usually surgical but that a trial of strict medical therapy is justified.

Retained Antrum and Zollinger-Ellison Syndrome

Recurrence of ulcer should always bring to mind the marked diathesis caused by retained gastric antrum and Zollinger-Ellison syndrome.[12] The cause of both of these conditions is continuous, uninhibited, hormonal stimulation of the parietal cell mass.

If, during the course of gastric resection, some of the antral tissue is included in the duodenal stump closure, this retained antrum will continuously elaborate gastrin because it is isolated in an alkalin medium. The treatment is surgical removal of this inadvertently retained tissue.

Zollinger and Ellison described a syndrome of intractable peptic ulcer associated with islet cell tumors of the pancreas. The extraction of the gastric secretagogue from islet cell tumors has reaffirmed the theory that the gastric hypersecretion in these patients is due to uninhibited, constant stimulation of the parietal cell mass by the tumor product. Zollinger and Ellison suggested that the preferred treatment of this disorder is removal of the end organ (total gastrectomy) because, at operation, 62% of these tumors were found to have spread beyond the pancreas. Facts helpful in the diagnosis are: (1) 25% of these cases have unusual sites of peptic ulceration, (2) 20% are associated with other adenomas, and (3) 25% include diarrhea secondary to gastric hypersecretion.

In both Zollinger-Ellison syndrome and retained gastric antrum, further support of the diagnosis is obtained by gastric analysis demonstrating near-maximal stimulation of the parietal cell mass at basal levels. In other words, the presence of a high basal acid secretion and an increase of less than 25% with maximal stimulation by histamine is suggestive of the diagnosis. The ultimate diagnostic test would be assay of secretagogue activity.

Gastric Ulcer

Approximately 25% of peptic ulcers are gastric in location. The peak incidence is one decade later than with duodenal ulcer and the sex ratio favors males by only 2 to 1. Theories of pathogenesis include, in addition to the gastrin mechanism of Dragstedt, (1) underlying antral mucosal atrophy and (2) breakdown in tissue resistance. Most gastric ulcers are located in the lesser curvature and are characterized by low-normal acid secretion. Space does not permit presentation of further clinical and epidemiologic data, but the more important factors in gastric ulceration appear to be considerably different from those of duodenal ulcer.[13] The most important fact that changes the management of gastric ulcer from that described for duodenal ulcer is the 7 to 10% incidence of carcinoma. The generally poorer response to medical therapy and the excellent results of operation also favor surgical treatment for a higher percentage of gastric ulcer patients.

In the case of the benign-appearing gastric ulcer with free acid, the "gastric ulcer ritual" must be observed. This includes hospitalization, strict medical management, roentgenologic evidence of healing, and a cooperative patient who understands the need for follow-up. All of these steps are necessary to avoid the danger of missed carcinoma in gastric ulcer. Cytology and gastroscopy are helpful, but both techniques have their share of false-positive and false-negative results. Eventually, 20 to 70% of patients with gastric ulcers will undergo gastric resection, depending on the enthusiasm of the attending physician for medical management.

Summary

The management of duodenal ulcer is generally based on what is known of the pathogenesis of the disease. Medical treatment is applicable in the majority of patients, but surgical treatment may be resorted to in an effort to change the gastric physiology. It is important to keep in mind the need for individual management of each patient and for avoidance of rigid patterns in this disease of little-known etiology.

when readings indicate hypertension

Time for Naturetin®

SQUIBB BENDROFLUMETHIAZIDE

to reduce blood pressure

In the management of your hypertensive patients, Naturetin is good therapy to start with, good therapy to stay with.

In mild hypertension, Naturetin lowers blood pressure gradually toward normotensive levels. In long-term therapy, Naturetin may keep blood pressure low—for months, sometimes years. When used in combination with other antihypertensive agents, blood pressure often falls further—and lower doses of both drugs are usually possible.

Clinical trials have proven Naturetin effective—without serious side effects.[1,2] And, when used to treat patients with cardiac edema and hypertension, "in no instance did the concentration of serum potassium fall below 3.1 mEq. per liter."[3] (Normal range for serum potassium: 3.5-5.0 mEq./liter).[4]

When readings indicate hypertension, start with Naturetin, stay with Naturetin.

Contraindications: Severe renal impairment; previous hypersensitivity.

Warning: Ulcerative small bowel lesions have occurred with potassium-containing thiazide preparations or with enteric-coated potassium salts supplementally. Stop medication if abdominal pain, distension, nausea, vomiting, or G.I. bleeding occur.

Precautions: The dosage of ganglionic blocking agents, veratrum, or hydralazine when used concomitantly must be reduced by at least 50% to avoid orthostatic hypotension. Electrolyte disturbances are possible in cirrhotic or digitalized patients.

Side Effects: Bendroflumethiazide may cause increases in serum uric acid, unmask diabetes, increase glycemia and glycosuria in diabetic patients and may cause hypochloremic alkalosis, hypokalemia; cramps, pruritus, paresthesias, and rashes may occur.

Supplied: Naturetin (Squibb Bendroflumethiazide) 5 mg. and 2.5 mg. tablets. Also available—Naturetin c̄ K [Squibb Bendroflumethiazide (5 or 2.5 mg.) with Potassium Chloride (500 mg.)]. For full information, see Product Brief.

Tumor Conference

A Changing Parotid Tumor

THE USUAL CLINICAL history of a parotid gland tumor is that a mass in the parotid steadily increases in size until the patient seeks medical attention. In over 95 parotid masses seen in the past 10 years at our hospital, only one showed a fluctuation in size. The unusual history and findings in this case illustrate a number of facts about a papillary cystadenoma lymphomatosum of the parotid gland. For convenience this tumor is usually given the eponym of "Warthin's tumor," although Albrecht and Artz[1] described three cases of it some 19 years before Warthin's description.[2]

Case Report

The patient was a 42-year-old lawyer who was admitted to the Minneapolis Veterans Administration Hospital because of a mass below his right ear.

Six years previously he had been admitted to this hospital with a 6 x 6 cm. mass at the angle of the right mandible, below the ear, presumably in the tail of the parotid gland. Eight weeks prior to this first admission, the patient had had an episode of chills and fever which he took to be a recurrence of "malaria." Two weeks later he noted the gradually enlarging mass below his ear. The enlargement continued over the subsequent six weeks. He had no pain or signs of facial nerve involvement. The leukocyte count was 8,850 with a normal differential count. A sialogram showed only beading and decrease in the size of the smaller parotid ducts, suggesting some minimal diffuse inflammation. The mass did not significantly displace any of the ducts. During the course of his work-up, the mass decreased noticeably in size without any treatment; therefore surgery was postponed. Over the next two weeks the mass continued to get smaller until at the time of discharge it was only 2 x 2 cm. in size. On the patient's return to clinic two weeks later, no mass could be found, and it was presumed that the mass had been entirely inflammatory. He was followed at three-monthly intervals for two years, during which period no mass was detected.

On his most recent admission (six years later) he had a 3 x 3 cm. mass in the same area, which had been slowly increasing in size over seven months. On examination, a 3 x 3 cm. mass could be felt in the lower pole of the right parotid gland. X-rays of the area showed a 1-2 mm. calcific density overlying the right mandible, possibly a stone.

At operation the discrete mass was found to be located in the lower pole of the parotid gland. A superficial parotidectomy was done. The surgical specimen contained a 3 x 3 x 3 cm. cystic mass with a dense connective tissue capsule. On cut section this structure contained thick mucopurulent yellowish fluid, a culture of which grew out only diphtheroids. There was a 1.5 mm. stone in one of the minor salivary ducts 1.5 cm. anterior to the mass. Frozen sections were reported to show an infected papillary cystadenoma lymphomatosum. A microscopic section of the cyst wall is seen in Figure 1. There are numerous papillary folds, pseudostratified columnar epithelium, and large areas with squamous metaplasia of the epithelium. Numerous lymphocytes are seen in the connective tissue stroma; occasional reactive follicles also appear. There

Continued

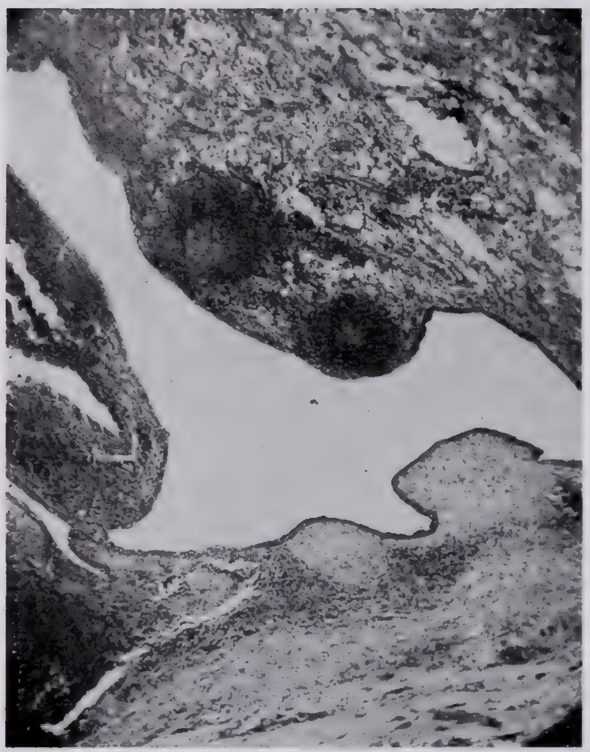

Fig. 1 — A photomicrograph of the tumor from the case discussed showing the papillary structure, the thick fibrous capsule, the diffuse inflammation, and the partial destruction of the papillary cystadenoma lymphomatosum.

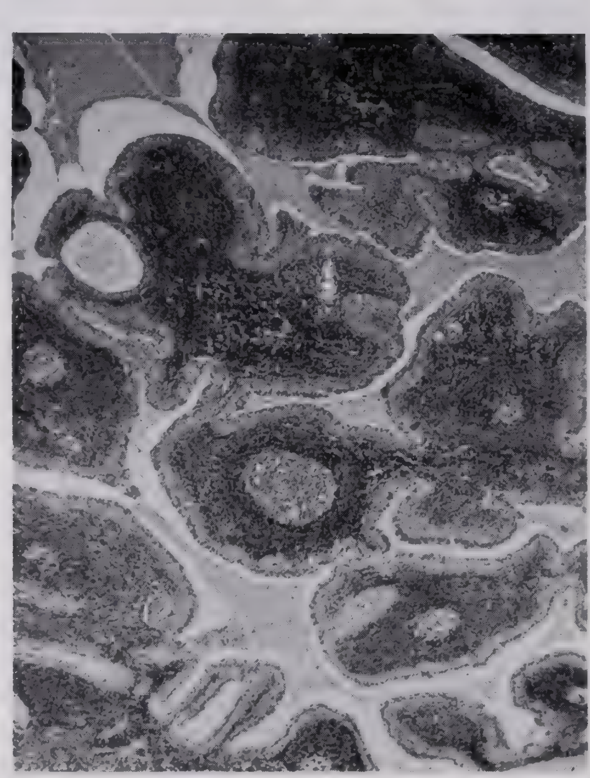

Fig. 2 — A typical papillary cystadenoma lymphomatosum from another case. The characteristic papillary structure and epithelium overlying a dense lymphoid stroma are seen. Note the reactive lymphoid follicles.

is an acute inflammatory infiltrate containing both PMNs and occasional eosinophils, the inflammation extending into the capsule. This tumor was an infected papillary cystadenoma lymphomatosum.

The patient's recovery was uneventful.

Comments

This case was interpreted as a small papillary cystadenoma lymphomatosum which has been involved in an inflammatory process on two occasions, once six years ago and again on the recent admission. The findings in both episodes are different from the typical clinical and laboratory findings of acute parotitis.

The most recent episode eventuated in an infected papillary cystadenoma lymphomatosum with partial destruction of the tumor and inflammatory infiltration of the residual tumor. Exactly what part the small ductal stone played is not clear. However, since there was some evidence of a healed parotitis in the area of the tumor, it is tempting to speculate that the localized parotitis drained to the lymphatic stroma of the tumor.

A more typical example of papillary cystadenoma lymphomatosum from another case is seen in Figure 2. The usual histology is characterized by papillary, pink, epithelial-lined cystic spaces containing pink granular material. The underlying dense blue lymphoid stroma frequently contains reactive follicles, suggestive of the functional capacity of the lymphoid tissue. The epithelium in the usual papillary cystadenoma lymphomatosum is seen on closer view (Figure 3) to have a double layer of nuclei in a pseudostratified epithelium. The nuclei nearer the surface are darker, smaller and slightly crenated. In comparing this typical picture with Figure 1, it can be seen that the inflammation has left only vestiges of the typical papillary cystadenoma lymphomatosum.

This case illustrated several facts about papillary cystadenoma lymphomatosum which are of interest.

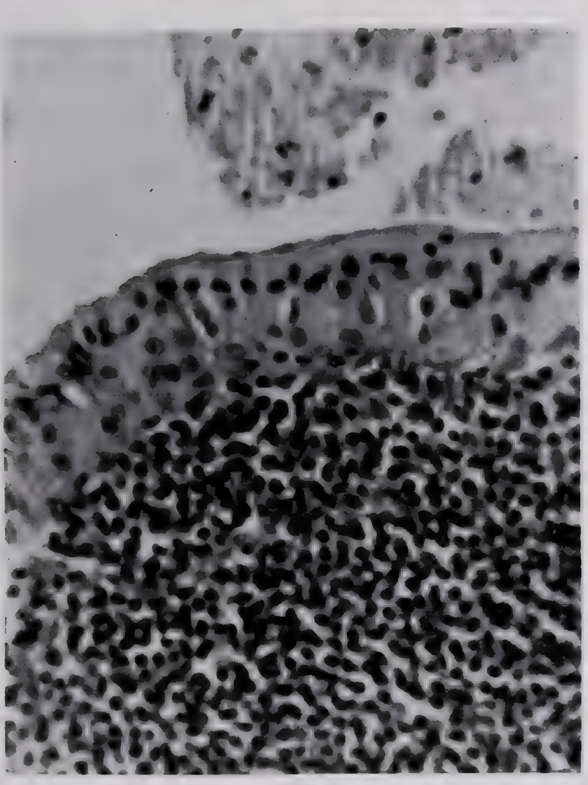

Fig. 3 — A high-powered view of the pseudostratified epithelium, showing the double layer of nuclei.

First: This tumor probably arises in salivary ductal tissue which for some reason or other becomes trapped in the functionally normal lymphatic tissue present in the tail of the parotid. This is evidenced in the frequency of reactive follicles in the stroma of a papillary cystadenoma lymphomatosum, in the occasional finding of granulomata in the tumor as well as in adjacent normal lymph nodes, and in the involvement in several cases of lymphoid stroma of a papillary cystadenoma lymphomatosum in systemic lymphomas. Thompson and Bryant have critically reviewed the histogenesis of this tumor.[3] The frequency with which ductal elements can be found in parotid lymph nodes is well known to pathologists.

Second: Papillary cystadenoma lymphomatosum is almost exclusively a tumor of males. In several large series it was found in a 10 to 1 ratio.[1,4,5] In the Minneapolis Veterans Administration Hospital population, a recent review[6] showed that papillary cystadenoma lymphomatosum was the second most common parotid tumor, comprising a surprising 25% of all parotid tumors — an incidence five times that usually reported. This incidence reflected the predominance of papillary cystadenoma lymphomatosum in males and a relative reduction in the number of pleomorphic adenomas (benign mixed tumor) encountered more fre-

Continued

quently in women. Papillary cystadenoma lymphomatosum, which has a peak occurrence one to two decades later in life than plemorphic adenoma, would also tend to be more frequent in an elderly veteran population.

Third: Papillary cystadenoma lymphomatosum is always found in the parotid gland, usually located in the lower pole of the gland.[1,6] This probably reflects the necessity of the juxtaposition of salivary ducts and lymph nodes in the origin of the tumor. The parotid gland is the one major salivary gland which has lymph nodes imbedded within its substance.

Fourth: This tumor is virtually always benign, only two well documented cases of *primary* malignancy being acceptable to a recent critical review of the malignant potential of the papillary cystadenoma lymphomatosum.[7]

The management of this tumor is that of any other parotid mass, since the papillary cystadenoma lymphomatosum has no distinguishing characteristics which will allow accurate preoperative identification and distinction from the malignant parotid tumors. Removal by superficial parotidectomy was adequate for excisional biopsy and definitive management in our cases, since all tumors were located in the lower superficial portions of the gland.

President's Letter

Continued from page 1055.

Every delegate and every officer is familiar with the post-meeting question, "What were you fellows trying to do to us down there"? There are no "You fellows" nor any "us". There are only members of the Minnesota State Medical Association with common interests and common concerns but varying degrees of participation. Increasing that participation is the task of the Committee on Scientific Assembly; improving the participation is the acceptance by individual physicians of the soundness of Disraeli's comment.

Clinical Path Conference

Recurrent Cardiac Failure Associated with Calcified Aortic Valve

Dr. Thomas E. Layman

First admission — A 73-year-old man was admitted to the hospital in a depressed state and with symptoms suggestive of duodenal ulcer. The blood pressure was 140 mm. Hg., systolic and 60, diastolic. The results of the remainder of the physical examination were within normal limits. No cardiac murmurs were heard. The patient was seen by a psychiatrist who made a diagnosis of a neurotic depressive reaction.

Roentgenographic examination of the upper gastrointestinal tract demonstrated an active duodenal ulcer. The results of the urinalysis were normal. The hemoglobin concentration in the blood was 13.6 grams per 100 ml. The leukocyte count of the blood was 6,300 cells per cubic mm. The blood urea nitrogen was 21 mg., the fasting blood glucose was 68 mg., and the total serum cholesterol was 274 mg., each per 100 ml.

During this period of hospitalization the patient was treated for the duodenal ulcer with isopropamide and prochlorperazine in the form of Combid® spansules twice daily. A second roentgenographic study of the upper gastrointestinal tract performed one month after the first demonstrated no abnormalities. Over a period of one month the patient received 12 electroshock convulsive treatments for the depressive reaction with apparently good results. He was discharged nine weeks after admission.

Second admission (*eight months later*) — The patient was again admitted for a depressive reaction and for cardiac decompensation. He complained of shortness of breath which had been present for the two weeks prior to admission. In addition, he demonstrated a depression and traits of a withdrawn personality similar to those shown during his first admission.

The results of the physical examination were unchanged from those of the first admission. A roentgenographic study of the upper gastrointestinal tract was performed and demonstrated a marked, nonobstructive deformity of the duodenal bulb. There was no demonstrable evidence of ulcer.

Continued

The results of the urinalysis were completely normal. The hemoglobin content of the blood was 12.4 grams per 100 ml. The erythrocyte sedimentation rate was 43 mm. per hour.

During his hospitalization the patient was treated with digitalis leaf and an intramuscular mercurial diuretic, in addition to Ritalin® in doses of 40 mg. three times daily and Stelazine® in doses of 5 mg. five times daily. On this regimen the patient lost eight pounds in weight, the greatest loss occurring within the first two weeks of hospitalization. No electroshock therapy was given. The patient was discharged seven weeks following admission.

Third admission (*3½ months later*) — The patient was again admitted for a depressive reaction. He had been maintained on digitalis leaf from the time of the second admission. The results of the physical examination revealed evidence of recent loss of weight. The blood pressure was 124 mm. Hg., systolic and 70 mm. Hg., diastolic. The results of the remainder of the physical examination were within normal limits. The results of the urinalysis were normal. The hemoglobin content of the blood was 12.3 grams per 100 ml. The total blood leukocyte count was 4,150 cells per cubic mm. The erythrocyte sedimentation rate was 38 mm. per hour. The blood urea nitrogen and total serum cholesterol were normal. The protein bound iodine was reported as 9.5 micrograms per 100 ml. (this test was not repeated). The erythrocyte sedimentation rate tested one week following the first was 10 mm. per hour.

During this hospitalization the patient was treated with methyl testosterone, 25 mg. per day and digitalis leaf. He was discharged from the hospital one month after admission.

Fourth admission (*three months later*) — The patient again was admitted for chronic depression and for increasing dyspnea during the prior two weeks. The blood pressure was 140 mm. Hg., systolic and 100, diastolic. A cardiac murmur was heard for the first time at the base of the heart over the aortic area and was characterized as a loud systolic murmur. Moist rales were noted at both pulmonary bases. The results of the remainder of the physical examination were within normal limits.

The patient was treated with digitalis leaf and a mercurial diuretic given intramuscularly. With this therapy he lost a total of 15 pounds, the greatest loss occurring within the first five days of hospitalization. He was discharged to a nursing home after 12 days of therapy in the hospital.

Fifth (*final*) *admission* (*13 days later*) — The patient was returned to the hospital from the nursing home because of increasingly severe dyspnea, a productive cough, peripheral edema and peripheral cyanosis. The blood pressure was 150 mm. Hg., systolic and 90, diastolic. He was markedly emaciated, dyspneic, pale and cyanotic. Examination of the thorax revealed the presence of bilateral pleural effusions; there were moist rales at both pulmonary bases. The heart rate was 80 beats per minute and regular. A loud systolic ejection murmur was heard at the base of the heart in the region of the aortic valve, and the extremities demonstrated ++ pitting edema. Except for a specific gravity of 1.005, the results of the urinalysis were negative. The blood hemoglobin content and total blood leukocyte count were normal; the blood urea nitrogen was 27 mg. per 100 ml., and the total serum protein was 7.4 gm. per 100 ml. with albumin constituting 3.3 gm. and globulin, 4.1 gm. of the total.

The patient was treated with daily intramuscular mercurial diuretics, digitalis leaf and multiple vitamins.

A right thoracentesis to remove evident fluid was attempted but was not successful.

The patient was discharged from the hospital 19 days after admission, returning to the nursing home. While in the nursing home he continued to demonstrate evidence of marked congestive cardiac failure with signs and symptoms of pulmonary congestion and pleural effusion. He suddenly expired two weeks following his discharge from the hospital.

Electrocardiograms made during the patient's first and last hospitalizations are illustrative of the many made during the course of his five admissions. Intervening electrocardiograms are transitional between the first taken (Figure 1-a) and the last taken (Figure 1-b). His first electrocardiogram (Figure 1-a) demonstrates a sinus rhythm with a P-R interval of 0.20 second. Shallow Q waves, 0.03 second in duration, are present in leads II, aVF, V_5 and V_6. In lead III, a QS pattern is present. The T waves in leads I, aVL, V_5 and V_6 are negative, while the T wave in leads II, aVF and V_4 is diphasic. The mean electrical axis is +20°.

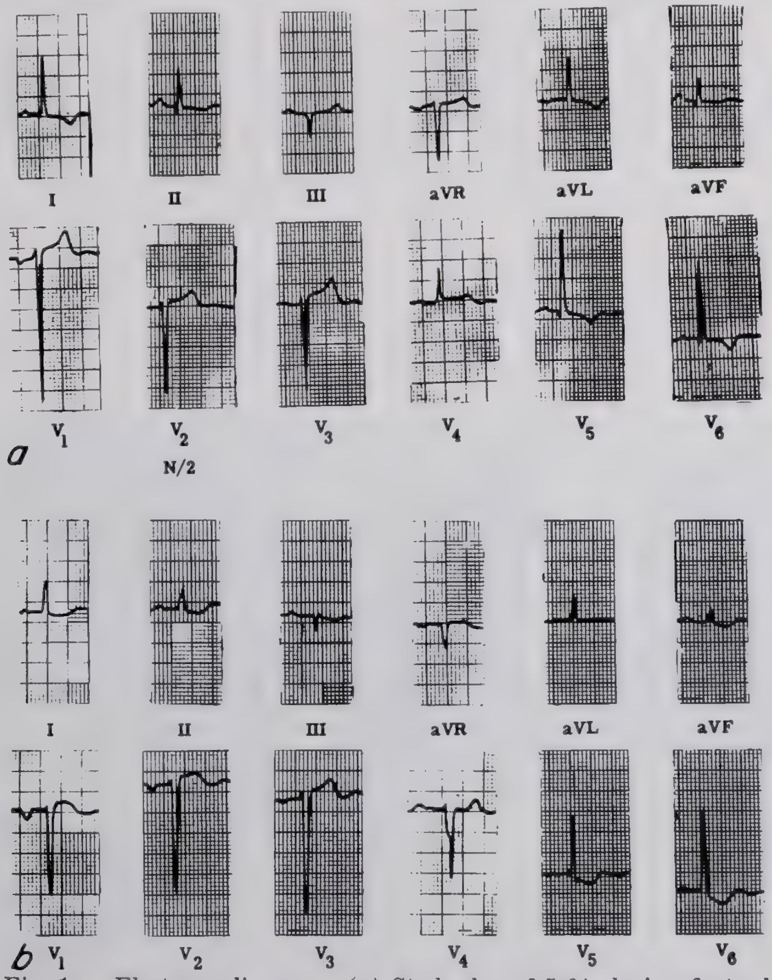

Fig. 1 — Electrocardiograms. *(a)* Study done 6-5-64, during first admission. *(b)* Study done 2-1-66, during fifth admission, ten weeks before the death of the patient.

Continued

The last electrocardiogram demonstrated sinus rhythm. In this (Figure 1-b) there was a P-R interval of 0.24 second. The small Q wave in leads II, aVF, V_5 and V_6 seen in the first admission has disappeared, while the QS pattern in lead III persists. The QRS complexes in leads II, aVF and V_4 are slurred, although the duration is normal, being 0.09 second. The T waves in leads I, II, aVR, aVF and V_1-V_6 are flattened and slightly diphasic, while minimal ST segmental sagging or elevation is apparent in the same leads. The mean electrical axis is $-5°$. At this time the P waves in leads V_1 and V_2 are wide and more negative than before.

Roentgenographic Findings

Dr. John B. Coleman

This thoracic roentgenogram, dated June 5, 1964, was made at the time of the patient's admission for a gastrointestinal problem (Figure 2). The most striking findings are the massive calcification in the aortic valvular area and the lack of much cardiac enlargement. We see that the heart is somewhat enlarged to the left and downward with a total transverse diameter of 14.7 cm. and a cardiothoracic ratio of only 42 per cent. Though the ratio is within accepted limits of normal, the impression is of some degree of enlargement. There is no evidence of left atrial enlargement. The hilar and intrapulmonary vessels are normal. The aortic caliber is also normal, and there is no unusual tortuosity. The lungs are clear. Considering the patient's age, this is a good looking thorax, except for the calcification and slight cardiac enlargement.

The rest of my comments pertain to selected films from subsequent admissions up to the time of the patient's death (Figure 3). On April 28, 1965 (Figure 3-a), the hilar and intrapulmonary vessels are generally enlarged, consistent with left heart failure, and the lower third of each pulmonary field is so dense that the cardiac outline and the diaphragm are obscured. There is fluid in both pleural spaces, more on the right than

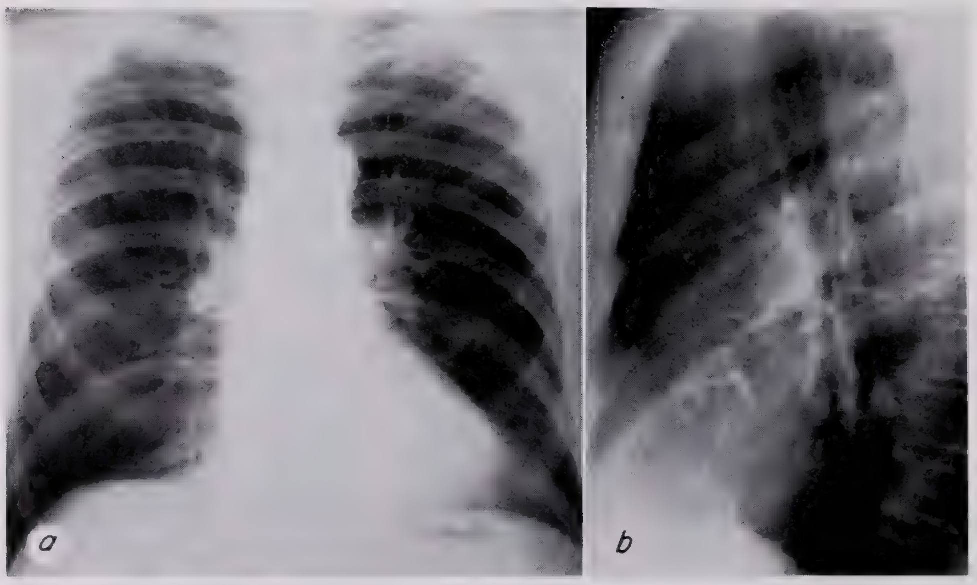

Fig. 2 — Thoracic roentgenogram made during the first admission (6-5-64). *(a)* Frontal view and *(b)* Lateral view. Calcification of the aortic valve. A calcific spur extends to the anterior region of the mitral valve.

on the left. Pulmonary consolidation is also present, and, while we may expect that it is accounted for in part by edema, we must consider in our differential the possibility of bilateral basilar pneumonia, atelectasis, or massive infarction. The heart is not likely greatly enlarged in spite of the severe degree of the other findings; this may reflect recent digitalization, but it also makes us wonder whether some associated cause such as renal failure may contribute to the vascular congestion and effusion.

In 1966, a film made on February 1 (Figure 3-b) reveals similar marked density of the lower pulmonary fields with bilateral effusion, which is greater in amount than before. Again we are impressed that the heart is not greatly dilated, though we cannot, of course, outline it distinctly. In the periphery of the lower aspects of the lung, we see the horizontal lines of congested lymphatic channels which help us so often in the diagnosis of chronic cardiac failure. I would estimate that the liver is not enlarged enough to elevate the right leaf of the diaphragm. On February 8 (Figure 3-c) the density in the bases of both sides of the thorax have largely disappeared; fluid remains in the right pleural space. The lungs have an appearance of over-distention, and there is no vascular overfilling as might result from left-sided cardiac failure. The heart is not larger than it was in 1964. Now for the first time, we observe a triangle of dense pulmonary tissue with its base appearing at the right hilum. In the lateral view this was shown to represent the middle lobe. The findings are characteristic of almost total collapse of the lobe. There is nothing else to indicate its cause, whether due to obstruction or to shrinkage from a chronic intrinsic disease process.

Our last roentgenographic examination was performed on March 14, 1966, and the findings were similar to those apparent six weeks earlier (Figure 3-b). The bases were extremely dense, the heart and diaphragm obscured and the peripheral pulmonary vasculature perhaps slightly increased.

Discussion

Dr. James N. Karnegis

The major symptoms as given in the protocol appear to be of psychiatric, gastrointestinal and cardiac natures. There is no informa-

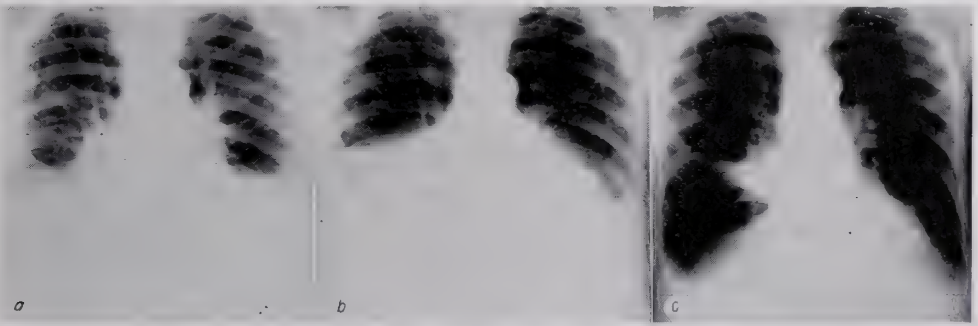

Fig. 3 — Thoracic roentgenograms made subsequent to first admission. *(a)* (4-28-65). Approximately eleven months subsequent to the roentgenograms shown in Figure 2. *(b)* (2-1-66). Roentgenogram made approximately nine months after that shown in *a*. *(c)* (2-8-66). Roentgenogram made about one week after that shown in *b* and approximately nine weeks prior to the death of the patient.

Continued

tion regarding this elderly man's past history so that we do not know if he had had psychiatric or other difficulties prior to his first admission, nor do we know anything about his state of health in the past.

There was ample evidence on the first admission to indicate cardiac disease. The aortic valve was calcified on thoracic roentgenography. The first electrocardiogram showed left ventricular hypertrophy with strain. Later, the patient was dyspneic, showed an increased cardiac shadow, pulmonary congestion and pleural effusion. He lost weight and improved on diuretics. The pattern, however, repeated itself until on the last admission there were cyanosis, edema, pleural effusion and a basal systolic ejection murmur. This course continued until death.

These considerations seem to lead to the inescapable conclusion that the patient had calcific aortic stenosis. The etiology of the aortic valvular disease could be rheumatic. However, since there is no evidence of mitral valvular disease, the lesion could be the result of a congenital deformity, such as a bicuspid aortic valve.

The calcific aortic stenosis may have been associated with other complications. The murmur was not heard until the last two admissions. It is possible that it might have been repeatedly missed, but changing murmurs suggest bacterial endocarditis. There is, however, no support for that possibility in the information given. Pleural effusion and pulmonary infiltration occurred. We recognize that chronic congestive cardiac failure predisposes to the development of pulmonary emboli. It is known that myocardial infarction is rare, even in severe aortic stenosis, unless there is coexistent coronary arterial disease.

Although the diagnosis of calcific aortic stenosis seems secure, there are many unusual features. It is true that some patients with this lesion live beyond 70 years of age, but most become symptomatic in the fifth and sixth decades. The typical blood pressure of severe aortic stenosis is not described. The valve was heavily calcified, as seen in the roentgenogram, and it seems curious that auscultation apparently persistently failed to reveal any of the characteristic findings of stenosis of the aortic valve. Also, the total elapsed time from the onset of cardiac failure to death was only about seven months. This indicates a very precipitous course if resulting from aortic stenosis, since the average survival time after the onset of congestive cardiac failure in this disease is usually about two years.

The pulmonary findings are also unusual for aortic stenosis. Cardiomegaly and pleural effusion are consistent with that lesion, but the parenchymal infiltrate and collapse of the right middle lobe do not fit very well.

It is difficult to explain the psychiatric and gastrointestinal symptoms on the basis of the patient's aortic stenosis. Of course, they may be entirely unrelated. But the usual cerebral symptom of tight aortic stenosis is syncope, and that was not present in this case. Furthermore, both the mental depression and the abdominal symptoms antedated the clinical appearance of the cardiac disease. In addition, the elevated erythrocyte sedimentation rate remains unexplained.

The picture is not entirely consistent with the diagnosis of calcific aortic stenosis alone. It seems that we must also consider the possibility that the patient had some additional disease process. Although we do not know anything about the man's past psychiatric history, we do know that his mental state was a severe problem in his last 15 months of life. The development of mental changes and/or epileptic seizures in the adult should always suggest the necessity of ruling out a cerebral tumor. It is well known that lesions of the frontal lobe of the brain, although difficult to diagnose early, may cause the patient to present with psychiatric symptoms. If this patient did have a brain tumor, it would be more likely metastatic than primary, since pulmonary and abdominal symptoms were also present. The bronchi are the most common source for tumors which metastasize to the brain. There is some suspicion of a bronchogenic carcinoma, since the middle lobe was collapsed. Metastatic carcinoma could explain the pleural effusions and pulmonary infiltrates. The second electrocardiogram shows a diminished voltage as well as a change in the QRS patterns. The Q waves are lost in leads II, aVF, and in the precordial leads, and a splintered complex is present in leads II and aVF. These findings would be consistent with extension of a tumor to the heart and pericardium and with the presence of pericardial effusion. Metastases to the liver and the abdominal cavity would explain the gastrointestinal symptoms and the reversed A/G ratio. The marked cachexia is entirely consistent with a rampaging malignancy. An elevated erythrocyte sedimentation rate is commonly found with cancer, and it can return to normal in the presence of congestive cardiac failure. The value for protein bound iodine in the blood is high and, if correct, remains unexplained. There is no other evidence for thyrotoxicosis. Isopropamide does not cause elevated blood levels of protein bound iodine when determined by the ash method.

Another possibility that must be mentioned is that a primary tumor could have arisen in the abdomen. A gastric or pancreatic carcinoma with metastases to the lungs, heart and brain would be consistent with the findings. This, however, is less likely than a bronchial carcinoma, since the latter is the most common tumor to metastasize to the pericardium and heart. A definite diagnosis of a malignancy cannot be made from the available information, but the suspicion that one is present must be entertained.

In conclusion, it seems clear that the patient had calcific aortic stenosis, perhaps on the basis of a congenital deformity, such as a bicuspid aortic valve; metastatic carcinoma must be considered and cannot be excluded by the data. If a malignant tumor were present, the primary would most likely have been a bronchogenic carcinoma.

Dr. Layman

The patient exhibited depressive behavior for about 20 years prior to the first admission described.

Dr. Karnegis

With the information just presented, I would be less inclined to consider an organic cerebral lesion, and, in turn, this makes somewhat less likely the possibility of a malignant tumor being present in this case.

Dr. Layman

Dr. Edwards, would you present the necropsy findings and close the discussion.

Continued

Dr. Jesse E. Edwards

The pathologic findings of significance included lesions in the heart, features of congestive cardiac failure and changes in the right lung. No tumor was present.

The heart was grossly enlarged, weighing 660 grams. The main basis for the enlargement was left ventricular hypertrophy. Three areas in the heart were of particular interest, namely, the aortic valve, the mitral valve and the papillary muscles of the left ventricle. The aortic valve displayed a fixed and narrowed orifice having a "tear-drop" shape and measuring 1.8 cm. in length and 0.7 cm. at its greatest wall. The abnormalities of the aortic valve were derived from the presence of a congenital malformation and secondary acquired calcification. The congenital malformation of the valve was in the form of a unicommissural, unicuspid valve (Figure 4). Superficially resembling a congenital bicuspid state, the aortic valve was equipped with but one commissure and one cusp. This became apparent when one started at one side of the commissure and proceeded along the cusp. As the cusp approached the aortic wall opposite the commissure, it turned upon itself and proceeded toward the commissure where it inserted to complete the single commissure. Opposite the commissure a broad calcified raphe extended from the aortic wall onto the cusp. A second, less bulky raphe was also present. I have designated this type of aortic valvular deformity as a unicommissural, unicuspid valve.[1] It has the characteristics of being intrinsically stenotic as, except for the single commissure, the valve resembles the dome-shaped valve of congenital pulmonary stenosis. Qualitatively the valve is like that which is usually present in symptomatic congenital pulmonary valvular stenosis. In the case presented in this conference the orifice of the malformed valve was relatively wide and consequently may not have been significantly malfunctional until calcium became deposited in it. The calcium was heavily deposited in the valvular substance and a large spur of calcium extended downward onto the ventricular aspect of the anterior mitral leaflet.

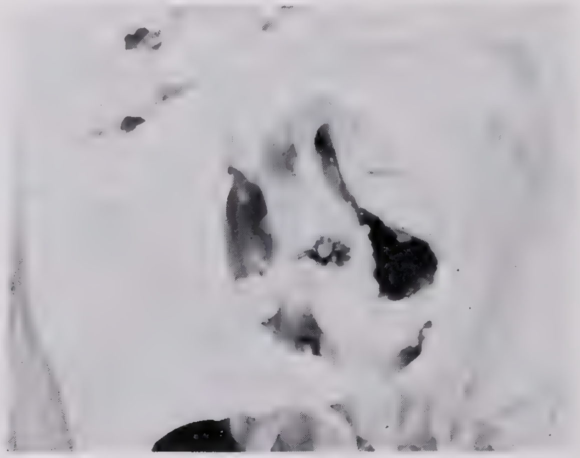

Fig. 4 — Aortic valve from above. The structure is that of a modified dome (unicommissural, unicuspid aortic valve) with secondary calcification. The orifice is markedly restricted in size and exhibits a "tear-drop" shape.

With the acquisition of calcific deposits, the aortic valve became rigid. This may have increased the degree of obstruction, and it may also have introduced an element of aortic insufficiency. The latter point is explained as follows. In the stages when the valve was fibrous, its relatively freely movable structure may have prevented incompetence by elements of the dome-shaped tissue impinging upon themselves to effect a flutter-valve action. With rigidity developing on the basis of calcification, the latter function was probably lost, yielding a stenotic valve with a fixed orifice. The consequence of the acquired aortic insufficiency was to accentuate the degree of aortic stenosis. This assumption is based upon the principle that the degree of stenosis of a valve is determined not only by its absolute caliber but also by the amount of blood flowing through the valve in a given period of time. Obviously, for a given volume of forward flow, more blood passes through the aortic valve during systole when aortic insufficiency is present than when the aortic valve is competent.

The mitral valve was also the site of a malformation with secondary acquired disease (Figure 5). This was characterized by a solitary accessory chorda tendinea which had extended from the ventricular septum to the ventricular aspect of the center of the anterior leaflet. At the time of our examination of the heart at necropsy, this chorda was found detached near its septal attachment. The free end of the chorda was tapered and discolored tan, a picture of acquired rupture. Histologically, no signs of bacterial infection were evident. The evidence suggests that the presence of the accessory mitral cord and its acquired rupture had probably played only minor, if any, roles in causing any disturbance of the circulation. The position of the accessory cord corresponds with the position of accessory cords that attach to the cleft anterior mitral leaflet in the malformation known as persistent common atrioventricular canal.[2] In this case with intact valvular leaflets and the usual papillary muscle and cordal mechanisms, one cannot attribute any useful function by the anomalous cord when it was intact. In that state the cord could only have been detrimental by causing unusual restraint upon the anterior leaflet and being responsible for mitral insufficiency. The clinical and

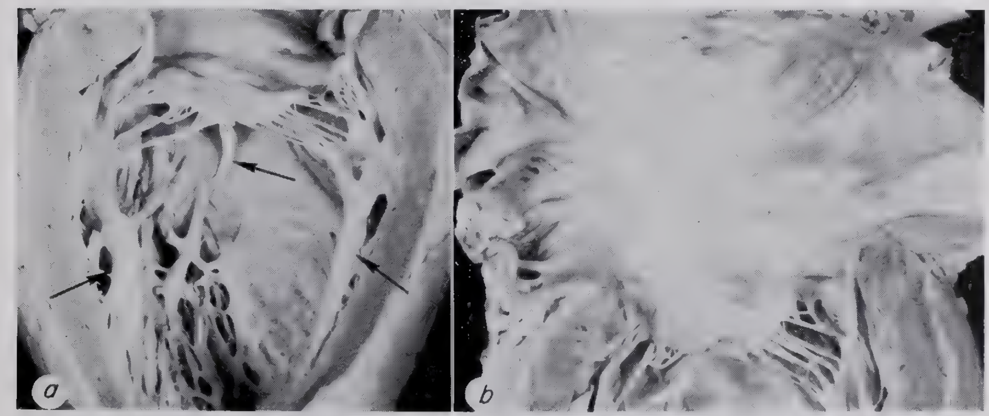

Fig. 5 — *(a)* Left atrium and left ventricle exposing the mitral valve. From center of the anterior leaflet of the mitral valve an anomalous cord (point of upper arrow) extends toward the ventricular septum from which it had ruptured. In addition to left ventricular hypertrophy, the papillary muscles (lower arrows) are atrophic on the basis of infarction and secondary scarring. *(b)* Left atrium and mitral valve. The cord shown in *a* is partly out of view. The basic support of the mitral valve through the two papillary muscles is normal, although atrophy of the papillary muscles is present. The left atrium is dilated.

Continued

pathologic evidence does not suggest that this patient suffered from primary mitral insufficiency throughout his life. Moreover, one cannot envision rupture of the anomalous mitral cord being responsible for any loss of essential restraint upon the mitral valve in view of the presence of the usual cords and papillary muscles. One must accept the presence of the anomalous mitral cord and its rupture as interesting, yet functionally unimportant features in this case.

Quite another matter pertains to the papillary muscles. The papillary muscles of the left ventricle were atrophic on the basis of loss of muscle and replacement by scar tissue (Figures 5 and 6). This change, which is considered to be the result of infarction of the papillary muscles, occurred in the absence of any coronary atherosclerosis. The coronary arteries were singularly devoid of any such lesions! Fragmentation of the diseased aortic valve may occur and lead to embolism within the myocardium and in other sites supplied by the systemic circulation. No such lesions were found to explain the infarction of the papillary muscles in this case.

We are strongly inclined to attribute the infarction of the papillary muscles in our case to the left ventricular hypertrophy associated with aortic valvular disease. The basis for this opinion resides in our observations that in the presence of hypertrophy of the left ventricle and in spite of normal coronary arteries, the left ventricular papillary muscles exhibit a strong tendency to infarction. In studies by Moller and associates from our institutions, infarction of papillary muscles and secondary mitral insufficiency were commonly observed in infants with symptomatic congenital aortic stenosis.[3,4] Extension of these studies by Drs. Ernesto Arosemena, James Moller and myself to adults with left ventricular hypertrophy of various causes show a predilection for infarction of the papillary muscles of hypertrophied left ventricles.[5]

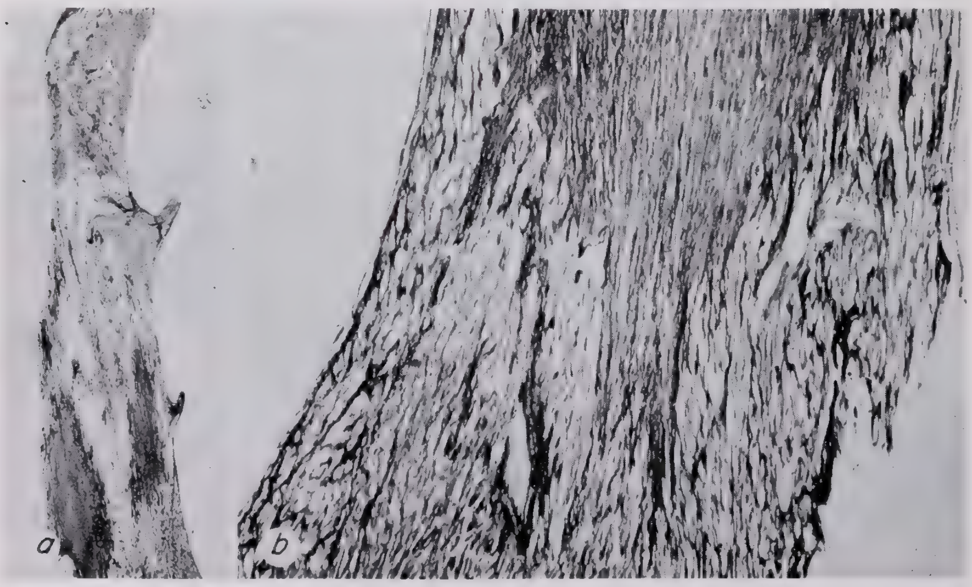

Fig. 6 — Photomicrographs of posteromedial papillary muscle of the left ventricle. *(a)* Low-power view shows extensive zones of scarring (black) resulting from infarction. Infarction is also focally present in pale areas. Elastic tissue stain; X 5. *(b)* Close-up view of junction of scar (black) and noninfarcted muscle at the base of the papillary muscle. Elastic tissue stain; X 25.

Infarction of papillary muscles, whether complicating coronary arterial disease or left ventricular hypertrophy, may cause mitral insufficiency.[6] Enlargement of the left atrium in this case may be taken as a probable anatomic sign of mitral insufficiency. We should conclude that the latter process had resulted from the observed infarction of the papillary muscles.

The middle lobe of the right lung was consolidated. Histologically it showed a picture of alveolar hemorrhage and focal scarring consistent with healed infarction.

Diagnosis

Calcification complicating congenital unicuspid aortic stenosis with secondary infarction of papillary muscles of left ventricle.

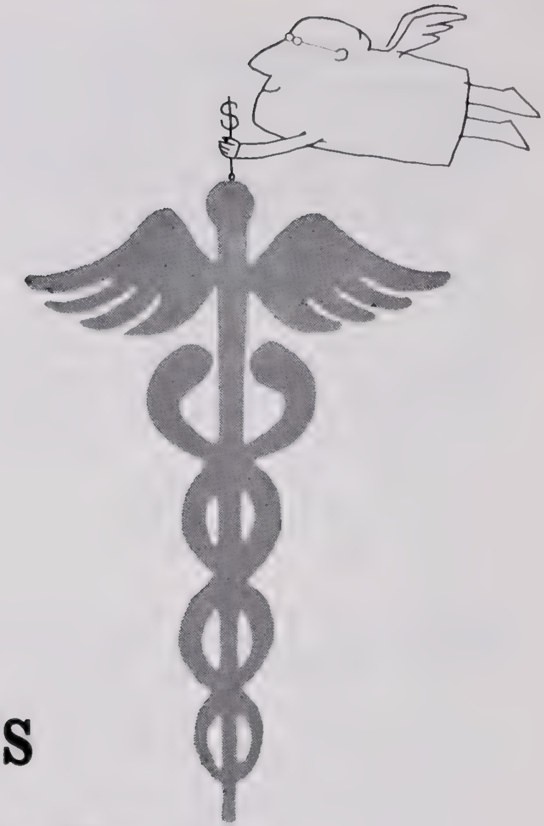
On Wine From Sanitatis Salernitanum

White Muskadell, and Candie wine, and Greek,
Do make men's wits and bodies grosse and fat;
Red wine doth make the voyce oft-time to seeke,
And hath a binding qualitie to that;
Canarie, Madera, both are like
To make one leane indeed; (but wot you what)
Who say they make one leane, would make one laffe,
They meane, they make one leane upon a staffe.
Wine, Women, Baths, by Art or Nature warme,
Us'd or abus'd do men much good or harme.

When death consents to let us live a long time, it takes successively as hostages all those we have loved. — Ninon de Lenclos



Why do more Minnesota Doctors insure with The St. Paul?

Probably because our Professional Liability coverage is so thorough.

Really broad coverage. Fewer exclusions, so interpretations are no problem. The price is likely to be nice, too.

To get the folder that tells all about it concisely, write.

The St. Paul is the approved carrier for the State Medical Association here . . . and in more states than any other single insurance company. It must be something we offer!

Want to see just 1 insurance man and still be fully insured? Use our St. Paul Multicover Plan. Same agent as for Liability. He's in the Yellow Pages.

Grand Rounds

Hypertensive Crisis and Tranylcypromine (Parnate)

JOHN CROSSON, M.D.
Medical Resident

TRANYLCYPROMINE (PARNATE) is one of the many monoamine oxidase inhibitors presently being used for the treatment of depression and hypertension. In the early 1960s there were several reports in the British literature of severe hypertensive reactions, some fatal, in patients taking tranylcypromine.[7,9] In 1964, because of these reports, tranylcypromine was removed from the American market for several months. However, it was later returned for clinical use with the idea that it would be safe if proper precautions were taken. To understand the pathophysiology underlying the hypertensive reactions it is necessary to understand the chemistry of monoamine oxidase and the inhibitors of this enzyme.

Chemistry

Monoamine oxidase is an enzyme that catalyzes the oxidation of amines to the corresponding aldehyde, peroxide and ammonia.[1] This enzyme was first demonstrated in conjunction with the metabolism of tyramine in 1928 by Hare.[2] He demonstrated an enzyme, which he called tyramine oxidase, which catalyzes the deamination of tyramine to the corresponding aldehyde and ammonia. This is the same enzyme that deaminates epinephrine and norepinephrine as well as other amines.[3] The amino group must be attached to a terminal carbon atom to be metabolized by this enzyme. Thus ephedrine and amphetamine are not acted on by monoamine oxidase.[3]

History

Monoamine Oxidase Inhibitors

In the early 1950s iproniazid and isoniazid were found to be effective

---

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, Minneapolis, April 5, 1966.

Continued

in the treatment of tuberculosis. Iproniazid is a monoamine oxidase inhibitor but isoniazid is not. In a study comparing the relative potency of these two drugs, Ogilvie described the first hypertensive crisis with monoamine oxidase inhibitors. He observed 42 patients with tuberculosis treated with iproniazid and 47 treated with isoniazid and found toxic reactions in 30 of 42 on iproniazid and in only seven of 47 on isoniazid. He described attacks of severe headache, palpitations, flushes, sweats and hypertension in four of the patients on iproniazid and therefore concluded that iproniazid was more effective in treating tuberculosis, but also much more toxic than isoniazid.[5] Iproniazid was later taken off the American market because of hepatotoxicity.

In 1960 Lurie and Salzer described attacks of severe headache and a marked rise in blood pressure in two of 84 patients taking tranylcypromine.[6] Lees and Burke observed similar attacks in 11 of 60 outpatients taking the drug. They described these as attacks of palpitation, throbbing pain in the head, dyspnea, bradycardia, sweating, and vomiting. Interestingly, they observed, before the mechanism was known, that these attacks were similar to those in patients with pheochromocytoma.[7]

Tyramine in Cheese

In a letter to the editor, Blackwell relates that he had been told by a pharmacist friend of his that the pharmacist's wife, who was on parnate, had attacks of headaches and hypertension after eating cheese.[8] Blackwell was skeptical, but he took dietary histories on 12 of his patients who had hypertensive crises while on monoamine oxidase inhibitors. He felt that the history was unreliable in two; but of the other ten, he found that eight had eaten cheddar cheese within one-half to two hours before the onset of the attack. One of the others had eaten Marmite, a sandwich spread later shown to produce these attacks. His description of the attacks is remarkably similar to that described by our patient. The attack begins with a forceful heart beat (palpitation), followed by a pulsating of the vessels in the neck. Soon a choking sensation and sweating develop, followed by a throbbing headache in the occipital and temporal region. The headache lasts one to three hours. On examination both systolic and diastolic hypertension as well as bradycardia is noted. Three of his 12 patients had intracranial bleeding.[9]

The importance of cheese was pointed out by Bethune et al. in their retrospective study. They reviewed the records of 126 outpatients treated with monoamine oxidase inhibitors prior to September 7, 1963, and found 23 episodes of hypertension and headaches for an incidence of 18.2 per cent. On September 7, 1963, they started warning their patients of the dangers of cheese with monoamine oxidase inhibitors. After this date, 244 patients were treated with monoamine oxidase inhibitors, and there were only eight hypertensive episodes for an incidence of 3.3 per cent. In five of these eight the warning had not been heeded.[10]

Mendels, however, recorded the blood pressure weekly in 150 patients on parnate, followed for 15 months, and he found no episodes of hypertension.[11]

Asatoor was the first to implicate tyramine in cheese as the cause of these hypertensive crises. He reviewed the previous reports showing that tyramine is present in significant amounts in some cheeses. He then measured the amount of tyramine in Camembert cheese and found it to be 0.2 per cent. He fed Camembert cheese to normal subjects and measured the urinary excretion of p-hydroxyphenylacetic acid, a compound formed from tyramine by the action of monoamine oxidase and aldehyde oxidase. He found a 200-per cent increase in the urinary excretion of this acid in two hours, indicating that the tyramine in the cheese is absorbed and subsequently metabolized. He then proposed that monoamine oxidase inhibitors would inhibit the metabolism of tyramine, allowing it to circulate in an active form.[12]

Blackwell and Mabbitt measured the tyramine content in certain cheeses and found that some of the English cheddar cheeses that had been shown to produce hypertensive crises had tyramine contents ranging from 480 to 953 mcg. per gram of cheese. The tyramine content was seen to vary a great deal from cheese to cheese and to be nonexistent in some. Tyramine is produced by the action of bacteria on tyrasine; so the shorter the time required to ripen the cheese the less tyramine is present.[13] New York cheddar cheese has a high concentration of tyramine. The only alcoholic beverage that has tyramine is Chianti wine.[14] Marmite, a yeast extract, has 1,500 mcg. tryamine per gram. As little as 4 grams of Marmite in a person taking monoamine oxidase inhibitors has been shown to produce hypertensive reactions.[15]

Horwitz found that tyramine was 10 to 100 times as effective in raising blood pressure after monoamine oxidase inhibitor administration. He studied seven patients with essential hypertension who had normal blood pressure in the hospital. He gave them intravenous tyramine in doses enough to raise the blood pressure 25 to 65 mm. Hg. In controls he found it took an average of 80 mgm. per hour, but in monoamine oxidase inhibitor-treated patients only 1.3 mgm. per hour to raise the blood pressure. Orally 250 mgm. tyramine produced a rise of 35 mm. Hg. in blood pressure in controls and 6 mgm. produced a significant rise in treated patients.[16]

Thus as little as 10 grams of cheese that contains 1 mgm. of tyramine per gram could easily produce hypertension in patients on monoamine oxidase inhibitors.

Tyramine presumably acts by releasing norepinephrine from the sympathetic nerve endings, so causing the hypertension.[17]

Catecholamine Metabolism

In order to further understand the role of tyramine and monoamine oxidase inhibitors in producing hypertensive crises it is necessary to understand how catecholamines are stored and metabolized. There are two major pathways for the metabolism of catecholamines: one utilizing an enzyme called catechol-o-methyl transferase and the other utilizing monoamine oxidase. The catechol-o-methyl transferase pathway is the major pathway for the metabolism of catechol amines in man;[18] however, monoamine oxidase does play an important role. It is known that treatment in experimental animals with monoamine oxidase inhibitors leads to increased brain norepinephrine, even though the metabolism of exogenously administered norepinephrine is unaffected by these drugs.[18] It is currently accepted that norepinephrine is stored in several different ways in the neuron:

1. Stored in small granules in the cell in combination with adenosine

Continued

triphosphate — the stable pool.

2. Stored in the same granules but not combined with adenosine triphosphate — the mobile pool.

3. Stored outside the granules close to the terminal cell membrane and released by nerve stimulation.[4]

The Table shows that these different sources of norepinephrine are affected differently by monoamine oxidase. It is currently thought that monoamine oxidase, which is found in the mitochondrial fraction of the cell, acts only on intracellular norepinephrine and that catechol-o-methyl transferase is responsible for metabolism of norepinephrine once it is released from the cell. Thus nerve stimulation releases active norepinephrine into the synaptic junction where it exerts an effect, then is metabolized by catechol-o-methyl transferase. Similarly, tyramine acts by releasing the mobile fraction of norepinephrine directly into the circulation in an active form where it too is acted on by catechol-o-methyl transferase. Conversely, reserpine acts on the stable pool, releases norepinephrine from the granules intracellularly where it can be metabolized by monoamine oxidase and released into the circulation in an inactive form.[19] This explains why reserpine and tyramine, which both act by depleting peripheral stores of norepinephrine, have opposite actions. That tyramine and nerve stimulation affect different sources of norepinephrine has been shown by the fact that sympathetic nerve stimulation is carried on in the normal fashion even when norepinephrine has been maximally released by tyramine.[20] When monoamine oxidase inhibitors have been given, followed by reserpine to release norepinephrine, this released norepinephrine cannot be metabolized intracellularly as it normally would be; so it is released in an active form into the circulation.[19] This is born out experimentally in several different laboratory animals which show marked excitation instead of the usual depression with reserpine if they had previously been pretreated with monoamine oxidase inhibitors.[21]

The effect of tyramine in patients who have been on monoamine oxidase inhibitors is probably two-fold. First of all, monoamine oxidase is found in high concentration in the liver and intestines,[1] so that it is important in metabolizing administered tyramine. When this enzyme is inhibited, the tyramine circulates in the entire body in an active form. Secondly, monoamine oxidase is important in the intracellular metabolism of norepinephrine, so that when this enzyme is inhibited there is a buildup of

TABLE*

Norepinephrine Source	Metabolized by Monoamine Oxidase	Effect of Monoamine Oxidase Inhibitors

norepinephrine in the cells, part of which probably goes into the fraction released by tyramine, so that there is more norepinephrine to be released.

There is good evidence that the hypotensive effect of monoamine oxidase inhibitors is not related to the inhibition of this enzyme at all. Gessa and his co-workers feel that monoamine oxidase inhibitors act directly to prevent release of norepinephrine by sympathetic nerve impulses.[22]

Treatment

Workers have long noted the similarity between hypertensive crises with monoamine oxidase inhibitors and attacks associated with pheochromocytomas. The previous information on the mechanism of production of these hypertensive crises would suggest that the best treatment would be the use of alpha adrenergic blocking agents such as phentolamine.[1] In large series this has proven to be very effective in doses of 5 mgm. intravenously given carefully with frequent blood pressure checks until the pressure is in normal range.[10] Dibenzyline in dosage of 10 mgm. orally has also been used successfully.[10] On theoretical and experimental grounds reserpine should be avoided, as one might expect this drug to produce even greater increase in blood pressure. However, Moser and his co-workers, in studying the effects of isocarboxazid and reserpine in 43 hypertensive patients, found that there was no increase in blood pressure when reserpine was given to patients previously treated with the monoamine oxidase inhibitor.[23]

It should be pointed out that other drugs are potentiated by the use of monoamine oxidase inhibitors; these include narcotics, alcohol, barbiturates, insulin and tranquilizers. Particular care must be taken in using demerol in patients on monoamine oxidase inhibitors, as severe hypotension and respiratory depression have been seen with small doses of demerol. Also severe reactions of hypertension, seizures and hyperpyrexia have been seen using monoamine oxidase inhibitors and imipramine (Tofranil) at the same time.[1]

Case Report

A 53-year-old, white female nurse was hospitalized in December, 1965, with the chief complaint of headache and palpitations. She had a 10-month history of mild hypertension and was on tranylcypromine (Parnate) 10 mgm. b.i.d. and trifluoperazine (Stelazine) 2 mgm. b.i.d. The patient had felt essentially well until 6:45 p.m. of the day of admission when she experienced the sudden onset of palpitations, followed quickly by a severe occipital headache which progressed to a generalized headache. She took her pulse at that time and found it to be 52 per minute. She had difficulty seeing but finally was able to call for help.

When seen in the emergency room her blood pressure was 240/110. There was no vomiting but some nausea. On questioning, she said she had eaten some cheddar cheese soup 30 minutes prior to the onset of symptoms. This was the first time she had ever eaten this type of soup.

On admission to the ward her blood pressure was 210/140/90 and her pulse was 50 and regular. She did not appear acutely ill. Pupils were equal and reacted. Funduscopic examination was unremarkable. Neck was supple. Chest and abdomen were normal. Neurological examination was within normal limits. EKG showed only sinus bradycardia. Urinalysis and hemogram were normal. Skull films and chest x-ray were normal. The patient was treated with one 25 mgm. dose of apresoline, analgesics and bed rest. By the following morning her blood pressure was in normal range. By the second hospital day her headache was gone and she was discharged on the third day.

in treating topical infections, no need to sensitize the patient

USE 'POLYSPORIN'® brand
POLYMYXIN B-BACITRACIN
ANTIBIOTIC OINTMENT

broad-spectrum antibiotic therapy with minimum risk of sensitization

Caution: As with other antibiotic products, prolonged use may result in overgrowth of nonsusceptible organisms, including fungi. Appropriate measures should be taken if this occurs. **Contraindication:** This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.
Supplied: In ½ oz. and 1 oz. tubes

PRODUCT NEWS

Pentyex-MPL

As we study the geriatric patient, we find many of them require a cerebral stimulant for sustained treatment. Some of these patients are mildly confused, have memory defects and apathy. The action of the ingredients supplied in Pentylex Elixir has proved 100 per cent effective in over two-thirds of the patients treated on a continuing basis with pentylenetetrazol alone. Pentylex Elixir supplies (in a fine wine base) not only pentylenetetrazol but also thiamine, niacinamide and cyanocobalamin, other essentials often required by these patients.

Minnesota Pharmaceutical's Pentylex is also available in an injectable form which includes the liptotropic factors of choline, methionine, and inositol as well as B-12 and other B-complex factors.

Advances

Antibacterial Management of Infection Due to Gram-Negative Bacilli*

Part III. Use of Ampicillin, the Cephalosporins, Spectinomycin, and Chemotherapy

WILLIAM J. MARTIN, M.D.**
Rochester, Minnesota

Ampicillin

THE CORE of the penicillin molecule is 6-aminopenicillanic acid; differences among the penicillins depend on the nature of side chains attached to the core. By inhibiting the production of the mold, *Penicillium chrysogenum*, at the point at which only the unattached core has been produced, new penicillins have been semisynthesized, which reflect variations in the attached side chains. Ampicillin, which has an aminobenzyl side chain, is an example of a penicillin with this ability.

Ampicillin (Polycillin, Penbritin) is given orally or parenterally and is bactericidal against strains of *Escherichia coli, Proteus mirabilis, Salmonella, Shigella, Haemophilus influenzae* and *H. parainfluenzae, Brucella,* and some species of *Bacteroides.* However, it is ineffective against most *Proteus* organisms that are indole-positive and against *Klebsiella-Aerobacter* and *Pseudomonas* organisms. The emergence of resistant strains of *E. coli* and *Proteus* has been described in patients receiving ampicillin.

Ampicillin is not active against penicillin G-resistant staphylococci. The drug is somewhat less active than penicillin G against pneumonococci, streptococci, and *Neisseria,* and *Clostridium* organisms.

Results comparable to those obtained with previously available agents have been described in enteritis from *Shigella* and *Salmonella* organisms. However, some strains of *Salmonell*a are resistant to ampicillin on in-vitro testing. Fecal or urinary excretors of *Salmonella* organisms are more likely to respond to ampicillin than are biliary excretors. The response of biliary excretors in patients without cholelithiasis is better than it is in those with stones, but after cholecystectomy about 50% of the latter patients may be successfully treated. As yet, ampicillin has not displaced chloramphenicol as the drug of choice in typhoid fever. Urinary infections caused by *E. coli, P. mirabilis,* and enterococcus organisms have responded to ampicillin. Ampicillin has eradicated *Haemophilus influenzae* from the respiratory tracts of patients having chronic bronchitis and has been effective in pneumonia and meningitis caused by *H. influenzae.*

Dosage

Usually 250 and 500 mg. of ampicillin is given every four to six hours by the oral route. In serious infections, such as typhoid fever, 4 to 6 gm. is given daily until the fever has subsided, when the dosage may be reduced to 2 to 3 gm. daily for a total period of treatments of three to four weeks; however, some investigators have given typhoid carriers the higher dosage for as long as six weeks. It appears unnecessary to give ampicillin when the stomach is empty. As much as 6 gm. daily has been given intramuscularly or intravenously. On conjoint administration

**Mayo Clinic and Mayo Foundation: Section of Medicine.

of probenecid, serum levels of ampicillin are higher and better sustained.

Untoward Effects

Like other semisynthetic penicillins, ampicillin is cross-allergenic with the natural penicillins.

Aside from superinfection, untoward effects occur in about 5% of patients receiving ampicillin, but in only about 1% are these sufficiently severe to require cessation of therapy. Gastrointestinal irritation, including diarrhea, may occur after ampicillin is taken orally, and some patients complain of an unpleasant tasting eructation. As is well known, the penicillins can cause various skin reactions, glossitis, angioneurotic edema, eosinophilia, drug fever, anaphylaxis, and so forth. During ampicillin therapy, the serum glutamic oxaloacetic transaminase activity may be increased. In about 5% of patients, superinfection due to such organisms as *Klebsiella-Aerobacter, Pseudomonas,* and *Candida* have occurred; staphylococcal superinfection is theoretically possible.

The Cephalosporins

Cephalosporin C is an antibiotic elaborated by the fungus, *Cephalosporium.* By chemical removal and replacement of the aminoadipic acid side chain of cephalosporin C, semisynthetic compounds have been produced. The core of the cephalosporin molecule is 7-aminocephalosporanic acid. Of these partially synthesized cephalosporins, cephalothin (Keflin)[1] is commercially available, cephaloridine is currently under investigation, and cephaloglycin has given preliminary evidence of potential value. Cephalothin, cephaloridine and cephaloglycin appear to be only the initial drugs in a series which ultimately may rival the semisynthetic penicillins in numbers and variations.

Strains of *E. coli, P. mirabilis,* and *Salmonella* and *Shigella* organisms are usually sensitive to the cephalosporins, while *Klebsiella-Aerobacter* organisms and indole-positive *Proteus* ones may be insensitive. *Pseudomonas* and *Bacteroides* organisms are resistant. In general, gram-positive cocci are more sensitive to the cephalosporins than are gram-negative bacilli. Staphylococci, including penicillin G-resistant strains, pneumococci, and *Streptococcus pyogenes* and *S. viridans* are susceptible to the cephalosporins, but enterococci are often resistant.

Cephalothin and cephaloridine must be given parenterally and may be bactericidal against susceptible organisms. Cephalothin and cephaloridine are usually given in amounts of 0.5 to 1 gm. every four to six hours intramuscularly or intravenously. Cephalothin has been given intramuscularly for more than eight weeks, and 12 to 24 gm. has been administered intravenously for as long as two weeks. Cephaloridine has been given in amounts of 18 gm. for as long as a month. After reconstitution with diluent, cephalothin should be stored in the refrigerator and should not be used after 48 hours.

Untoward Effects

Untoward effects of cephalothin include thrombophlebitis when the drug is given intravenously for longer than two to three days, pain at the site of intramuscular injection, rash, fever, serum sickness, anaphylactoid reaction, transient neutropenia, eosinophilia, increased serum glutamic oxaloacetic transaminase activity, and increased azotemia. Untoward effects of cephaloridine include rash, fever, transient neutropenia, increased serum glutamic oxaloacetic transaminase, mild prolongation of prothrombin time, and probable nephrotoxicity. Superinfection from *Bacteroides, Klebsiella-Aerobacter,* or *Pseudomonas* organisms is possible with either cephalothin or cephaloridine. Cross-allergy between the cephalosporins and the penicillins has not been entirely excluded to date.

The cephalosporins, while resistant to penicillinase, may be degraded by cephalosporinase produced by certain bacteria, including strains of staphylococci and of bacilli found in the intestinal tract. If cephalosporinase-producing organisms constitute a future clinical problem, there is the possibility of synthesizing cephalosporinase-resistant cephalosporins.[2]

In the Management of Infections

It is difficult to evaluate precisely the position of cephalothin in the management of infections due to gram-negative bacilli currently, in part because of an apparent dichotomy between in-vitro susceptibilities and clinical results. That is to say, laboratory data would indicate that the drug is applicable in certain of these infections, and yet clinical response is delayed, incomplete, or occasionally absent. However, bacteremia due to bacilli originating in the intestinal tract, including *P. mirabilis* and *Klebsiella-Aerobacter* organisms, has responded to cephalothin. But, in coccal infections, cephalothin appears to be more established as an effective agent. Staphylococcal bacteremia, pneumonia, and osteomyelitis have responded to cephalothin. Pneumococcal pneumonia also is susceptible to the drug, and cephalothin may have special use in patients allergic to penicillin. Subacute bacterial endocarditis due to *S. viridans* has been managed successfully with cephalothin.

Cephaloridine[3,4] may be more potent than cephalothin against some gram-positive cocci, but conversely, cephaloridine may be less bactericidal than cephalothin against certain staphylococci and streptococci. The comparative activity of cephaloridine may be increased against strains of *E. coli,* but some studies have shown variable degrees of activity against *E. coli* and other Enterbacteriaceae. Sensitivity of *Klebsiella-Aerobacter* organisms to cephaloridine is found in less than 50% of strains. Strains of *Proteus* other than *P. mirabilis* may be no more sensitive to cephaloridine than they are to cephalothin. Cephaloridine may be active against *Salmonella* and *Shigella* but is inactive against *Bacteroides* and *Pseudomonas* organisms. As is true of cephalothin, not all strains of *Haemophilus influenzae* are sensitive to cephaloridine.

Cephaloridine is an "internal salt"; as a betaine it does not require either sodium or potassium to form a salt. In patients in whom the administration of sodium or potassium might be hazardous, cephaloridine would have an advantage over cephalothin. Also, cephaloridine may be less irritating to tissues; blood levels with cephaloridine at least equal those with cephalothin, but the duration of cephaloridine levels is considerably longer. From 30 to 40% of cephalothin is bound to serum proteins, but cephaloridine is unbound. The solubility of cephaloridine is greater than that of cephalothin, thus reducing the volume of diluent required for intramuscular injection.

Cephaloridine has been effective in serious staphylococcal infections, in bacteremia due to *E. coli,* and in pneumococcal bacteremia and meningitis. Given conjointly with streptomycin, the drug may be effective in endocarditis due to streptococcus mitis. However, some infections due to organisms that were sensitive on in-vitro testing have persisted despite treatment. Also in some patients drug-resistant mutants of the pathogen have appeared to emerge during treatment.

Since the paradox of in-vitro bacterial susceptibility and clinical ineffectiveness is shared to some degree by both cephalothin and cephaloridine, it has been proposed that the lesser pain on intramuscular injection of cephaloridine, the smaller volume of diluent required by cephaloridine, the more sustained levels of cephaloridine with less frequent injections, the fact that cephaloridine does not require sodium or potassium to form a salt, might make cephloridine more acceptable as a parenteral antibiotic than cephalothin. However, this proposal has not as yet been substantiated by clinical investigation. One potential objection to cephaloridine is that in preliminary clinical studies it was necessary to discontinue use of the drug in more than 10% of patients because of toxic reactions.

Cephaloglycin differs from cephalothin and cephaloridine in that it is absorbed after oral administration. In experimental animals the intestinal absorption of cephaloglycin appears to compare favorably with penicillin V.

Spectinomycin

Spectinomycin (Trobicin),[5,6] formerly called actinospectocin, is currently being investigated. The drug is active against strains of *E. coli, Klebsiella-Aerobacter, Proteus,* and *Salmonella* organisms. In addition, spectinomycin is active against strains of

Continued

staphylococci, streptococci (including enterococci), pneumococci, and organisms of *Neisseria.*

The drug is not well absorbed after oral administration and is given intramuscularly, usually in amounts of 0.5 gm. four times daily. In men having acute gonorrheal arthritis, a single injection of 2 gm. has been given, and results are reported to compare favorably with those of penicillin. Intramuscular injection of spectinomycin probably produces no more local pain than penicillin or chloramphenicol.

The Sulfonamides

Certain sulfonamides and allied preparations are used in specific conditions such as leprosy, ocular infections, and chronic ulcerative colitis. Aside from these preparations, the sulfonamides have use in: (1) selected infections of the urinary tract; (2) nocardiosis without involvement of the central nervous system (conjoint cycloserine-sulfonamide therapy may give an enhanced antinocardial effect), and South American blastomycosis (but in infections due to resistant strains, amphotericin B is preferred); (3) meningitis of meningococcal etiology, wherein either a sulfonamide or a penicillin has been used, and that due to pneumococci in which conjoint sulfonamide-penicillin therapy may be preferable (but today bacterial resistance should be excluded before a sulfonamide is employed as a single drug in meningococcal infections); (4) toxoplasmosis in which sulfadiazine is used conjointly with pyrimethamine (Daraprim); (5) shigellosis (but in areas where resistant strains are frequent, antibiotics such as a tetracycline or ampicillin are preferred); (6) certain infections due to members of the tribe Mimeae (but in those due to resistant strains, other therapy such as a tetracycline combined with kanamycin, polymyxin B, or colistin may be preferred); (7) lymphopathia venereum and chancroid (since sulfonamide therapy, unlike use of tetracycline, does not mask conjoint syphilis); (8) mild infections due to *H. influenzae* (but, in serious infections, other regimens, like streptomycin-tetracycline, chloramphenicol or ampicillin have been preferred); (9) glanders, and (10) prophylactically against recurrences of rheumatic fever in persons allergic to penicillin. In the past, 2 gm. of sulfadiazine were given for two to three days to carriers of meningococci, but currently, even when resistant strains are excluded, there is doubt about the efficacy of the regimen unless its duration is considerably increased.

Clinical Application

Of the multiple sulfonamide preparations commercially available, the following, grouped according to their usual clinical application, are representative: (1) those used for systemic effect, including sulfadiazine, sulfamerazine, and sulfamethazine, which are known collectively as the sulfapyrimidines and are sometimes employed in combination in attempts to lessen the likelihood of renal toxicity; (2) those used in urinary infections, including the short-acting drugs such as sulfisoxazole (Gantrisin), sulfisomidine (Elkosin), and sulfamethizole (Thiosulfil), which sometimes are also employed for systemic effect, and in addition the long-acting drugs exemplified by acetyl sulfamethoxypyridazine (Kynex), sulfaethidole (Sul-Spansion), and sulfadimethoxine (Madribon); and (3) those used for intestinal antisepsis including sulfaguanidine, phthalylsulfathiazole (Sulfathalidine), and succinylsulfathiazole (Sulfasuxidine), which are poorly absorbed on oral administration and hence have special enteric application.

Untoward Effects

Although the sulfonamides in current use are less toxic than those employed previously, on rare occasions they cause such untoward effects as drug fever, dermatitis, nephrotoxicity, blood dyscrasias, and allergic vasculitis. Cyanosis, anaphylaxis, hepatitis, peripheral neuritis, conjunctivitis, and serum sickness are uncommon today. Nausea, vomiting, photosensitivity, dizziness, and headache occur occasionally. Mental disturbances have occurred on use of the sulfapyrimidines. Administration of a sulfonamide to a woman near term may produce kernicterus in the fetus. Nephrotoxicity may reflect either precipitation of the acetylated derivative in the tubules or hypersensitivity; hypersensitivity may affect the kidney directly, producing a nephritic or nephrotic syndrome, or the reaction may be indirect via an angiitis of the kidney and other organs. Alkalinization of the urine may decrease crystallization, but it also increases the rate of drug excretion and lowers the blood concentration, requiring increased administration to produce bacteriostasis. Sulfisoxazole (Gantrisin) and sulfisomidine (Elkosin) are more soluble in urine of variable pH than are sulfadiazine and sulfamerazine. Special care may be required with sulfamethoxazole (Gantanol) to avoid crystalluria because of the high degree of acetylation of the drug in the urine. Cross-hypersensitivity to various sulfonamides is common.

Use of the sulfonamides may unmask or precipitate clinical manifestations of previously inactive processes in certain predisposed individuals. In patients having erythrocytes deficient in glucose-6-phosphate dehydrogenase, hemolytic anemia may occur, and in those having porphyria or lupus erythematosus, acute manifestations may be precipitated.

Because use of the long-acting sulfonamides appears to have resulted in development of Stevens-Johnson syndrome (erythema multiforme exudativum), it is advised that one first consider administration of a short-acting sulfonamide. Because it may take several days for the long-acting sulfonamides to be metabolized and excreted, it is thought this characteristic may contribute to the severity of adverse reactions in susceptible individuals. Over 100 cases of the complication have been reported to date and two thirds of the patients were children. This complication has had a mortality rate of about 25%.

Dosage and Route of Administration

Sulfonamides for systemic effect are given in a maximal oral dose of 4 to 6 gm/day, sometimes following an initial dose of 4 gm. In systemic infections, a blood concentration of sulfonamide of 10 to 15 mg/100 ml. is recommended.

In management of urinary infections, the short-acting sulfonamides are given in amounts of 0.5 to 1 gm. four times daily, whereas 0.5 to 2 gm. of the long-acting derivatives are administered once or twice daily. When the poorly absorbed sulfonamides are given to produce intestinal antisepsis, as much as 8 gm. daily is administered in divided doses.

The sodium salts of these drugs, such as sodium sulfadiazine and sodium sulfisoxazole, are given intravenously. Via this route, the usual initial dose is 3 to 4 gm., with 1 to 2 gm. being given every eight to 12 hours thereafter.

The Nitrofurans

Nitrofurantoin (Furadantin) is effective in the majority of acute uncomplicated infections of the urinary tract due to *E. coli*. The drug may also be useful in streptococcal and staphylococcal infections of the urinary tract but is less likely to be effective in those due to *Klebsiella-Aerobacter, Proteus,* and *Pseudomonas* organisms. The emergence of bacterial strains resistant to the drug has not been a problem.

The oral dose of nitrofurantoin is 50 to 100 mg. four times daily. There is a preparation for intravenous administration, but justifiable indications for its use are rare.

Untoward effects include nausea, vomiting, fever, and rashes. Transient alopecia, pleuropneumonitis, asthma, anaphylactoid reactions, jaundice, and polyneuropathy are less frequent. As with the use of fava beans, acetanilid, sulfonamides, and primaquine, patients having erythrocytes deficient in glucose-6-phosphate dehydrogenase may develop hemolytic anemia during therapy with nitrofurantoin.

A nitrofuran presently being investigated in the management of urinary infections is NF 246. The drug appears to be effective against *E. coli* organisms and streptococci, including enterococci, as well as against strains of *Proteus* organisms. It may be effective against *Klebsiella-Aerobacter* and *Salmonella* organisms, but appears to be ineffective against strains of *Pseudomonas*.

Continued

Furazolidone (Furoxone) is designed for oral use in cases of bacterial enteritis. Strains of *E. coli, Proteus, Salmonella,* and *Shigella* organisms as well as streptococci and staphylococci are said to be sensitive to the drug. A 100-mg. dose four times daily is recommended. Nausea, vomiting, headache, hemolytic anemia, and, after ingestion of alcohol, a disulfiramlike effect may occur.

Nitrofurazone (Furacin) is used in various forms, including powder, ointment, creams, suppositories, and solutions, in the management of surface infections. Preparations are available for the management of skin lesions, vaginitis, trigonitis and for optic, otic, and nasal instillation. Sensitization appears to be uncommon.

Furazolidone and nifuroxime (Tricofuron) are used in combination in suppository and powder forms for vaginitis due to *H. vaginalis, Trichomonas,* or *Candida.* Furazolidone is antibacterial and trichomonacidal, whereas nifuroxime is fungicidal.

Nalidixic Acid

Nalidixic acid (Neg-Gram), a naphthyridine derivative, is used as a urinary antiseptic and is active against strains of *E. coli, Klebsiella-Aerobacter,* and *Proteus* organisms but is usually ineffective against *Pseudomonas, Salmonella, Shigella,* and coccal organisms. Preferably, in-vitro bacterial susceptibility studies should be carried out before nalidixic acid is used.

A 0.5 to 1-gm. dose of the drug is given orally four times daily. After two weeks of therapy, it is recommended that the daily dose not exceed 2 gm. An intravenous preparation is being investigated.

Untoward effects include gastrointestinal irritation, rashes, fever, headache, photosensitivity, visual disturbances, stimulation of the nervous system and, conversely, somnolence. Possible cases of bleeding from the gastrointestinal tract have occurred, and it is suggested that nalidixic acid may decrease ventilation in patients with respiratory deficit. Eosinophilia, leukopenia, increased serum glutamic oxaloacetic transaminase activity, increased azotemia, and possible hepatotoxicity have been noted. Resistant bacterial strains may emerge during therapy. False-positive tests for urinary glucose, and possibly true glycosuria, may occur. Nalidixic acid may have an antipyretic action similar to aspirin.

The Methenamines

Methenamine mandelate, a salt of equimolecular quantities of methenamine and mandelic acid, is used in acute uncomplicated infections of the urinary tract. The mandelic acid component of methenamine mandelate helps acidify the urine, releasing formaldehyde from methenamine. The formaldehyde is antibacterial to both gram-negative and gram-positive organisms, but the drug has use mainly in enterococcal infections. Despite the mandelic acid component, supplemental acidification may be required, particularly with urea-splitting organisms.

A dose of 0.5 to 2 gm. of the drug is given orally three or four times daily.

Untoward effects include nausea, vomiting, diarrhea, and skin rashes. Dysuria and albuminuria are uncommon, and hematuria is rare.

Methenamine hippurate is a compound in which mandelic acid is replaced by hippuric acid; but currently the compound is available only for investigational use.

The Acidifying Agents

The acidifying agents include such drugs as methionine, ammonium chloride, ammonium mandelate, calcium mandelate, and ascorbic acid. However, in recent years, use of methionine has been emphasized.

Decrease of urinary pH and bacterial counts may follow use of 8 to 15 gm. of methionine daily. However, when more than 8 gm. of the agent is given per day, the patient may note the odor of hydrogen sulfide about his person. The sulfur in methionine is oxidized to sulfate and is excreted in the urine, making it acidic. To minimize the patient's complaints regarding the odor-producing effects of methionine, some workers avoid the use of higher drug doses by conjoint administration of other acidifying agents like ammonium chloride. If the urinary pH can be reduced to 5 or less by conjoint use of these agents, the desired antibacterial effect may be procured, but it is difficult to maintain such a pH without inducing metabolic acidosis. With the availability of other effective drugs such as the sulfonamides, nitrofurantoin, and nalidixic acid, such cumbersome regimens as are required in attempts at acidification have rare application today.

Use of an acid-ash diet or large quantities of cranberry juice (which contains quinolic acid) in attempts to render the urine acidic are also not in common use currently.

When attempts are made to keep the urine acidic, the patient is advised regarding restriction of his fluid intake to 1,200 ml. a day and the avoidance of foods (primarily citrus fruits) and drugs (such as sodium bicarbonate and milk of magnesia) which increase the alkalinity of the urine. Also, the patient should periodically determine, by means of nitrazine test paper, whether his urine is properly acidic.

In this regard, adjustment of urinary pH has been said to enhance the activity of certain drugs in addition to methenamine mandelate in the management of urinary infection.[7] Antibacterial activity of the tetracyclines, novobiocin, and cycloserine may also be augmented at acid pH, whereas penicillin, erythromycin, streptomycin, neomycin, kanamycin, and gentamicin may be more potent at an alkaline pH. It is said that results with sulfonamides and chloramphenicol vary with the organisms tested and that the action of nitrofurantoin may not be greatly influenced by adjustments of pH. However, the majority of clinicians ordinarily do not place great emphasis on adjustments of urinary pH by employment of these additional drugs.

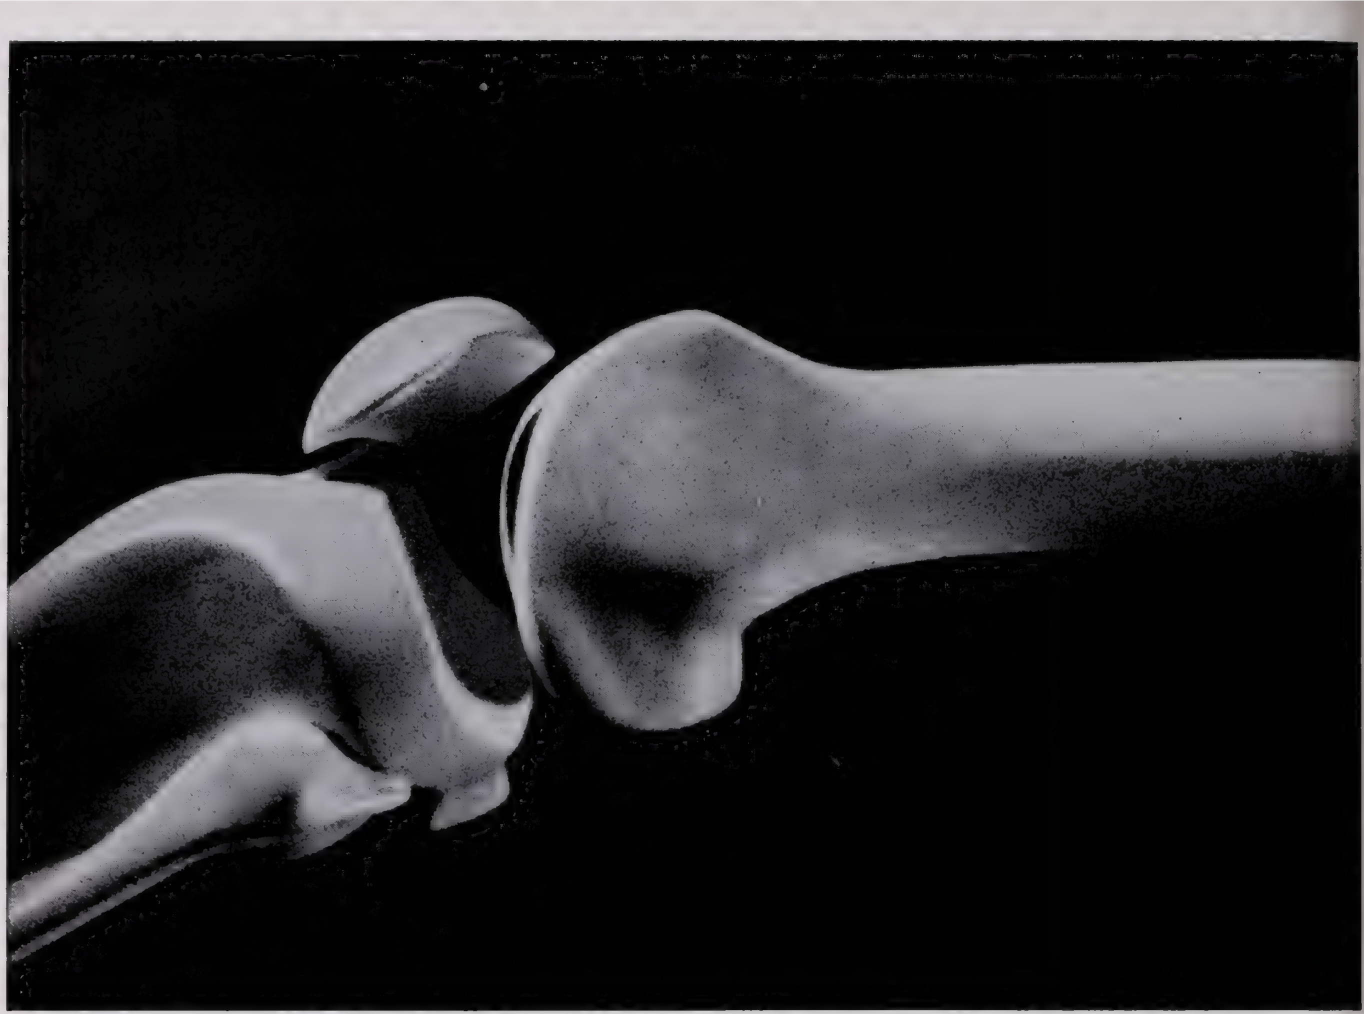
Your Age

In China, the 51st birthday is an occasion of great rejoicing, the 61st and 71st are progressively happier and grander; while a man able to celebrate his 81st birthday is looked upon as one specially favored by the gods.
— Lin Yutang

On Being a Patient

You cannot be a perfect doctor, till you have been a patient. You cannot be a perfect surgeon, till you have enjoyed in your own person some surgical experience. Enjoyed, I say, and stick to the word. Count the ways of enjoyment. To be the dear object of so much care and friendship, to be compassed about with hopes and prayers, is there no pleasure in that? To behave nicely, and nothing common do or mean, upon that memorable scene, but lie on the operating-table like Patience on a monument, is there no pleasure in that act of self-control? — Stephen Paget (1855-1926)



Butazolidin® alka

phenylbutazone	100 mg.
dried aluminum hydroxide gel	100 mg.
magnesium trisilicate	150 mg.
homatropine methylbromide	1.25 mg.

Usually works within 3 to 4 days in osteoarthritis

The trial period need not exceed 1 week. In contrast, the recommended trial period for indomethacin is *at least 1 month.*

That's why it's logical to start therapy with Butazolidin alka—you'll know quickly whether or not it works. And usually, it will.

A large number of investigators have reported major improvement in about 75% of cases. Some patients have gone into remission. Relief of stiffness and pain may be followed quickly by improved function and resolution of other signs of inflammation. And Butazolidin alka is well tolerated, especially since it contains antacids and an antispasmodic to minimize gastric upset.

Contraindications
Edema, danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile, or when other potent drugs are given concurrently. Large doses are contraindicated in patients with glaucoma.

Precautions
Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should be closely supervised and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools. Make regular blood counts. Use greater care in the elderly.

Warning
If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy.

Adverse Reactions
The most common are nausea, edema and drug rash. Hemodilution may cause moderate fall in red cell count. The drug may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, generalized allergic reaction, stomatitis, salivary gland enlargement, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently.

Dosage
The initial daily dosage in adults is 300-600 mg. daily in divided doses. In most instances, 400 mg. daily is sufficient. When improvement occurs, dosage should be decreased to the minimum effective level: this should not exceed 400 mg. daily, and is often achieved with only 100-200 mg. daily.

Also available: Butazolidin®,
brand of phenylbutazone
Tablets of 100 mg.

Medical Ethics

Can the Best be Better?

Address by Walter H. Judd, M.D.
First National Congress on Medical Ethics
Chicago, Illinois
March 5, 1966

The pursuit of excellence is a part of the spirit and tradition of America, and particularly of our profession. We instinctively feel that the best can always be made better.

Physicians are expected to assume this fact, but is it in keeping with the "honor and dignity" of the profession to make a public point of it and to make comparisons which might seem to reflect unfavorably on other professions?

To take stock of ourselves is why we are gathered in this First National Congress on Medical Ethics. We have been so preoccupied with our shortcomings — both those that are real and those not real but attributed to us in much of the public mind — that the picture can be seen in perspective only if we consider, at the outset, the bright and positive side also.

No less an authority than our distinguished morning speaker, Professor Everett Hughes, Ph.D., alluded to medicine as "the queen of the professions." The National Opinion Research Center, rating some 90 occupations, stated that the physician was rated most desirable of all except Justice of the United States Supreme Court. Diplomats, chemists and lawyers were tied for tenth place. Dentists, architects and county judges were tied for the fourteenth with psychologists and ministers tied for seventeenth. To the extent that other professions and the public as a whole rate the profession of medicine as the "best," why should this be so?

The ten Principles of Medical Ethics provide, I believe, the basic reasons. They are the blueprint and the foundation stones on which Medicine's house has been built. Both the principles and the accomplishments of the profession can be broken down into three categories: (1) the science of medicine; (2) the socioeconomics of medicine; and (3) the art of medicine.

The Science of Medicine

It is a well established ethical concept that every physician should aid in safeguarding the public and the profession against admission to it of those who are deficient in moral character, education, or professional competence.

In 1905, 28 per cent of all college graduates were entering the field of medicine. This situation prompted President Gilman of Johns Hopkins to remark that the medical student was likely to be "one son of the family too weak to labor on the farm, too stupid for the bar and too immoral for the pulpit." Only five medical schools required as much as two years of college as a prerequisite for matriculation. Today the Admission Committees of our 88 schools require at least three years, and almost all strongly recommend the completion of four years of college or its equivalent.

It is a fact that the cream of our youth has been attracted to the medical profession and the problem is not so much one of screening out undesirables as it is of making wise decisions in selecting from those who are already the "best," the ones who have the best character, best minds, best aptitudes, best motivation.

Continued

In order to make certain that there is no insurmountable economic barrier to admissions, the medical profession has supported scholarships and loan funds. Notably, the AMA in 1962 launched its medical education loan guarantee program which now has made 27,000 loans totaling more than $32 million to medical students, interns and residents.

The medical profession has taken the lead in securing the enactment in the states of Medical Practice Acts and Basic Science Acts and in supporting the state boards which administer them. It has established a National Board of Medical Examiners to prepare and administer qualifying examinations of high quality. It has also established the Educational Council for Foreign Medical Graduates to verify the credentials, evaluate the educational qualifications of foreign-trained physicians, and assist those who desire to advance their education in the United States.

The medical profession has recognized for years that instruction in medical school is only a prelude to a lifetime of striving for ever greater competence in the care of the sick. Thirty-seven of our fifty states require the completion of approved internship, and there is a yearly increase in residency training in the several specialties. The profession, again acting through its own agencies, has established the basic criteria for approval of internships and residencies, and on-site surveys are conducted to be sure the standards are met.

Although the "policing" actions by hospital medical staffs are well known to you, and Doctor Appel described them this morning, I venture to say that the public generally is unappreciative, because unaware, of the manner in which physicians voluntarily, as members of a hospital staff, impose requirements on themselves to insure a high quality of medical service. It is not the government; it is the medical staff that has always been and is the guardian of the high quality of medical service rendered in our hospitals. And when has any profession ever worked so hard to reduce its own income by eliminating or reducing the incidence of the diseases and suffering which it is the physician's livelihood to treat?

The Socioeconomics of Medicine

The profession was *not* prepared, either by tradition or training, for the explosion in the socioeconomic fabric of our society. The physician was accustomed to intimate doctor-patient relationship without the intervention of any third party. Three decades ago problems concerning the distribution of medical services were comparatively minimal. Today they are monumental. Notwithstanding these considerations — and despite the abuse that has oftentimes been directed at the medical profession because it did not embrace various schemes proposed for the intervention of third parties in the doctor-patient relationship — there is much accomplishment in this area.

Prepayment Plans

The profession has aided in the development of voluntary health insurance and prepayment plans as the best mechanism for paying for medical and hospital care. It has developed guides for evaluating medical care programs for those financially unable to pay their way. It has supported and cooperated with numerous programs at all levels of government designed to provide medical services to those who would not otherwise be able to obtain them. It has aided governmental programs for veterans, military personnel and their dependents and federal employees. Currently, it is studying various proposals for postpayment of medical bills to determine whether, operating under suitable safeguards, they too may reduce economic barriers to maximum health care.

Physicians' Fees

It has generally maintained physicians' charges at fair and reasonable levels. According to the 1964 Report of the Commission on the Cost of Medical Care, physicians' fees had risen only 112 per cent since 1935 as compared with 123 per cent in the over-all cost of living, 136 per cent in the total cost of medical care, and 480 per cent in hospital daily service charges.

The physician continues to observe the ethical guidelines that "his fees should be commensurate with the services rendered and the patient's ability to pay" and that "poverty of a patient * * * should command the gratuitous services of a physician." On the average, today's physician spends about one eighth of his time in providing free care. In 1960 physicians donated approximately $658 million in free medical care.

The physician insists that no payment plan interfere with or impair the free and full exercise of his medical judgment and skill or tend to cause a deterioration in the quality of medical care.

The Art of Medicine

May I group under "The Art of Medicine," those Principles of Medical Ethics which emphasize personal care of the patient and relationships between physicians.

These ethical guidelines may be summarized as follows: "The principal objective of the medical profession is to render service to humanity; reward or financial gain is a subordinate consideration. Fees should be fair. Unnecessary services or unnecessary facilities should not be provided or prescribed. Confidential communications between physician and patient should be respected. There should be mutual free choice between physicians and patients in entering into the doctor-patient relationship. A patient should be neither neglected nor abandoned. The physician should neither exaggerate nor minimize the gravity of a patient's condition. One physician should do nothing to diminish the trust reposed by a patient in his own physician. Physicians should uphold the honor and dignity of the medical profession and expose 'without hesitation, illegal or unethical conduct of fellow members of the profession.' Physicians should not solicit patients. 'There is but one code of ethics for all, be they group, clinic or individual and be they great and prominent or small and unknown.' "

There is, of course, no accurate yardstick by which the degree of compliance with these Principles may be measured, particularly those dealing with the physician's personal attention to his patient and his relation with his fellow-physicians. I am of the opinion that some of these principles are more wholeheartedly honored and observed by the profession today than ever before. Present public opinion obviously believes some are less well observed today than in former years. Undoubtedly this opinion is influenced by a nostalgia which magnifies the virtues of the past and also the shortcomings of the present as reflected in the isolated cases which come to public attention.

Yet we know that in our profession — as in others — there does exist a minority who must be controlled or disciplined if the moral tone of the profession is to be maintained at the highest level. This is the negative approach to medical ethics, but it is necessary and must be pursued courageously. That the medical profession is well aware of this fact is evidenced in part by the creation by the AMA Board of Trustees of a Medical Disciplinary Committee.

Disciplinary actions reported by state boards of medical examiners and state medical societies are, of course, only the visible part of the iceberg and give no indication of the volume of formal or informal grievance and disciplinary proceedings that occur each year. Most complaints against physicians are and should be handled by the physician himself in consultation with the complaining patient. When this does not bring satisfaction, or when the patient does not take his grievance directly to his physician, complaints are made to county and state medical societies and occasionally to the AMA, which invariably refers them back to the county medical society for attention. It is at this important level that all but a few of the more serious cases are handled, grievances resolved, and discipline imposed — usually without publicity.

Because medical society membership is so valuable and therefore coveted, the only sanction available to medical societies — that of expulsion or suspension from membership — is highly effective in most instances. In those cases in which the offender is not a member of a medical society, it may

Continued

be necessary to resort to sanctions authorized by state law.

While the record of the medical profession in the field of ethics and discipline justifies our feeling that it is the "best," we need to consider now some areas in which greater progress and improvement should be made. Even though ten new medical schools have been created since World War II and an additional fourteen are in process of being organized, the medical profession has a continuing obligation to take the lead in making certain there is always an adequate supply of properly-trained physicians to meet the needs of the public, both present and projected.

In the field of socioeconomics, it is obvious that the profession should try even more aggressively to propose and promote ways and means of meeting any public need for better distribution of medical services — always within the Principles of Medical Ethics.

Expectation of reward and financial return in accordance with one's merit and effort are powerful incentives to a physician, as to anyone else, to broaden his skills, improve his service, do his utmost for his patient. It is the public that has most to gain from provision of such incentives. They do not cheapen medical practice; they can elevate and enhance it. Unless medicine can remain attractive financially it will not attract the quality of students it must have if it is to be able to do what the public needs and wants from it. "In the practice of medicine a physician should limit the source of his professional income to medical services actually rendered by him, or under his supervision, to his patients."

Under this principle come those vexatious problems of physician-dispensing of drugs, eye glasses, etc., physician-ownership of pharmacies and drug repackaging companies, and the problem of fee splitting. It is in this sensitive area, particularly, that substance is more important than form — that the spirit must go beyond the letter. The medical profession has been challenged by legislation already enacted and the threat of additional legislation concerning the ownership of pharmacies and the dispensing of glasses. Although many of these attacks may be motivated more by economic than by ethical considerations, they cannot be ignored.

Obviously grievance and disciplinary mechanisms are valueless if they are not used. And clearly, there is room for improvement at this point. In general, "men of good conscience inherently know what is right and wrong, and what is to be done or to be avoided." But it does not follow that all ethical questions are so clear that men of good conscience will invariably agree on the proper answer. This Congress has been brought together in order that physicians, known for their exemplary integrity and public spiritedness may reason together, exchange experiences and viewpoints and find inspiration and motivation to rededicate a great profession at the peak of its powers to its finest traditions and its finest ideals. It is not enough just to refrain from behaving unethically. The profession needs a new pride, a new enthusiasm for excellence in the high duties entrusted to it that will make every physician *want* to behave *ethically* in the highest sense of the word, to go beyond the things required by rules or regulations — for the sheer satisfaction and joy of it. One cannot fail to see a serious challenge to the profession's freedom in the activities we witness in various quarters designed to persuade the people that their trust and confidence in medical matters would be better placed in government than in the medical profession. Unless the profession can *win* this competition for the primary confidence of the people, and maintain and strengthen the people's trust, it runs the grave risk of being converted into a public utility subject to the sort of regulations that are imposed on power and transportation.

The medical profession has enemies that it would be a mistake to regard as men of good will. On the other hand, not all of our critics have sinister or selfish motives. Some are within our own ranks and are seeking to stimulate the medical profession to rededicate itself to those principles which have made it peerless. Medicine is not alone in this struggle. Lawyers, ministers, dentists, engineers, architects and many others have more in common with us than they or we have yet realized in preserving professionalism as a most important part of American life. All professionals and the public alike must be constantly reminded of the important distinctions between a profession and a business, a trade or a union. It is essential for America's greatest future that a worthy medical profession remain free and strong, free practitioners of a high calling, not government-directed technicians. The key to this result is to merit and to command public trust and confidence. This does not come in the bargain basement. It must be deserved and it must be striven for. Its price, like that of liberty, is eternal vigilance. The key is in your hands. Take it home and unlock the doors to the future. May my last paragraph be the substance of the last paragraph of our oath. The wisdom of the immortal Hippocrates 2,300 years ago is relevant today:

"With our oath unviolated it will be granted to us to enjoy life and the practice of the art respected by all men at all times."

Tar Water

One of the most amusing incidents in the history of drugs is that of Bishop Berkeley's tar water. This precious fluid was made by stirring a gallon of water with a quart of tar and letting it stand forty-eight hours and pouring off the clear water. Absolutely nothing of any chemical significance had been dissolved out of the tar by the water but the smell of the tar clung to the fluid and so it was rather easy to persuade one's self that one must be taking something. Modern physicians use it occasionally for diluting lotions which are meant to prevent itching. Bishop Berkeley, however, found it a cure for everything. Yes, quite literally everything.

According to his own list it cured "gout and fevers, coughs, pleurisy, peripneumony, erysipelas, asthma, whether it came from the heart or the kidneys, indigestion, hysterics, mortification, scurvy, cachexia — which in that period usually meant cancer — hypochondria, liver disease, and dropsy," and was besides an excellent preservative for the teeth and gums. Too much of it could not be taken, it must be taken for at least a month before much effect could be expected of it and sometimes two or three months were necessary to bring about the beginning of relief from it.

Berkeley is the great idealist philosopher, one of the greatest thinkers perhaps in English philosophy, but he held two very odd opinions: namely, "that tar water was everything and that the whole material universe was nothing." Tar water is still with us, but that very fact only demonstrates beyond all doubt what a fool dear Bishop Berkeley made of himself over it.*

Rhubarb

Rhubarb has manifestly in it parts of contrary operations; parts that purge and parts that bind the body; and the first lie looser and the latter deeper, so that if you infuse rhubarb for an hour, and crush it well, it will purge better and bind the body less after the purging than if it stood twenty-four hours. — Lord Bacon

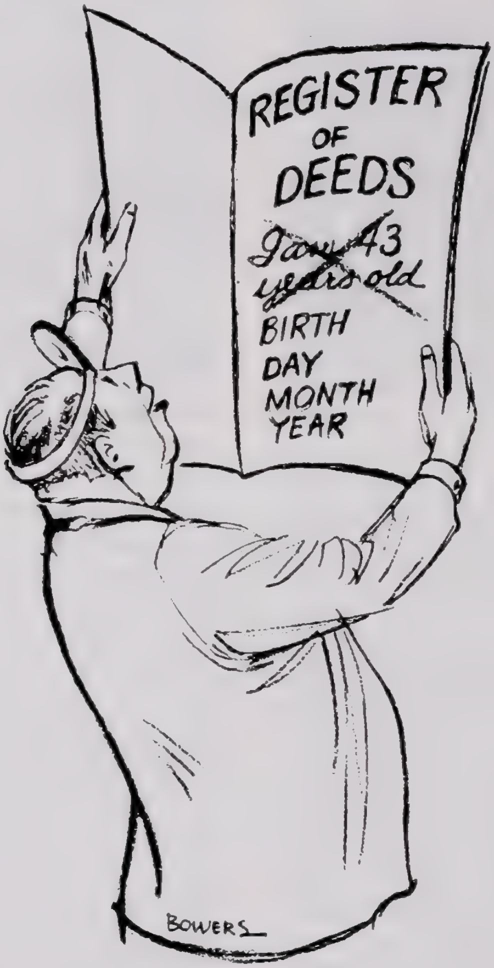
Better Service, Doctor?



Only Jack Benny gets away with being 39 all his life. He doesn't even use a birth date.

But in our efforts to improve service to our participating physicians and their patients, Blue Shield must have accurate birth dates on all claims for payment.

In fact, if your patient is a member of such groups as Federal Employees, Steel and/or J-Group, we cannot even begin to process the claim without the exact birth date.

Payment for incomplete reports might be delayed . . . or rejected. **Help us help you!**

Abstracts, Briefs and Commentaries

A PENETRATING WOUND OF THE ABDOMINAL AORTA

In a survey of penetrating wounds of the heart and aorta, those of the aorta prove to be the most dangerous. Of patients with aortic lesions only one in five lives long enough to get to the hospital; yet the mortality rate is only 30 per cent. Statistics indicate that 14 out of 100 patients with aortic wounds survive. At the Helsinki Hospital one man with this 14-per-cent chance survived.

Case Report

A mechanic, aged 17, drunk at the time, was stabbed twice. Ten minutes later he arrived at the hospital, with no first aid given en route. On arrival the patient was pale and shocked. The radial pulse was absent and the blood pressure too low to record. In the right thoracic wall below the breast was a 15-cm. stab wound. This wound did not involve the pleural cavity or the liver. A second wound, 2 cm. long, 1 cm. to the right of the umbilicus, was also present, from which spurted arterial blood. A blood-filled loop of intestine herniated through this wound due to intra-abdominal pressure. Treatment: An infusion of Mercrodex® was started in the cubital vein, followed by transfusions of O R uncrossed blood. Additional blood was given through four portals with the patient in deep Frelenburg position, and the blood pressure rose to 40/mm.

Under general anesthesia a long paramedian incision was made. Huge distended loops of intestine filled with blood erupted together with a powerful stream of arterial blood. By pressing the aorta against the spine with both hands, bleeding was arrested and the radial pulse could be palpated. The actual bleeding point was visualized and bleeding controlled by pressure at that point. A tangential cut 1.5 cm. was located on the right side of the aorta just above the inferior mesenteric artery. Forty minutes elapsed between the patient's entrance to the hospital and the control of the bleeding.

Using blood-vessel clamps for adequate exposure the aortic laceration was sutured with 4-0 silk. Search of the intestinal tract revealed a cut through the mesocolon and the duodenal wall, through which blood entered the stomach and the small intestine to the cecum. Two 2-cm. wounds of the duodenum were sutured. Shock and hypotonia did not disturb the intestinal or renal function, however. The operating time was four and a half hours. The patient received ten and a half liters of blood. After 26 days of hospitalization he was discharged. Four months later an aortogram was negative. Three months following the massive blood transfusions the patient developed serum hepatitis from which he recovered.

Discussion

Penetrating wounds of the aorta are usually caused by gunshot or stabbing. In Beall's 1960 series the abdominal aorta was involved in 14 patients out of 23, and of 14 treated by surgery four survived. Beall reports four

Continued

additional survivals found in the literature, making a total of eight known cases that survived.

If the patient's blood group is not known, O Rh negative blood is used. It is important not to change to the patient's own group if five units or more of the O group have been given. This danger persists for about two weeks.

An extremely critical moment and danger of exsanguination of the patient occur when the abdomen is opened. Immediate firm pressure of the aorta against the spine is imperative. After a period of waiting until the blood pressure takes an upward turn, further surgical procedures may be instituted. Vascular repair follows the application of vascular clamps. Clean lacerations may be sewn, but ragged lacerations may demand a patch graft or an aortic prosthesis of teflon or dacron. If a patient, just before arrival or on arrival, suffers a cardiac standstill, steps for resuscitation and surgical treatment are suggested.

ADDENDUM TO ARTERIAL INJURIES ASSOCIATED WITH FRACTURES

Makin, Howard, and Green have also reported on the necessity of a more aggressive approach when an arterial injury is a complication of a fracture or dislocation. They have shown in a study of 16 patients that when active treatment to the impaired circulation is attempted within the first 12 hours, the number of recoveries is much greater than when active therapy is delayed. Whenever arterial damage is suspected, they urgently suggest arteriography, which is to be followed immediately by operative restoration of the impaired arterial flow, because failure to restore the circulation results in permanent damage by ischemia or gangrene and eventual amputation. They make a plea suggesting that the training program for surgeons who expect to treat patients with injuries include the diagnostic and operative management of arterial injuries.

DIAGNOSIS OF DROWNING

Measurement of differences in plasma total solids between right and left heart blood by means of the total solids meter, a temperature-compensated hand refractometer, is shown to be at least as reliable as the measurement of osmolarity or chloride, especially as a test for fresh water drowning. This new, rapid, and simple technic has been evaluated in terms of other tests for fresh and sea water drowning, and it appears to provide a useful adjunct to present diagnostic methods.

A CAUSE FOR REPLANTATION FAILURE

Failure in limb replantation is often attributed to factors beyond the surgeon's control. Recently in the Milwaukee area a review of two attempts at preservation of a limb demonstrated that well known principles of vascular surgery may be unwittingly violated.

A few milliliters of a weak heparin solution injected through the artery wall was expected to prevent thrombosis in a limb without any circulation. Perfusing a limb for at least 15 minutes to flush out thrombi was not accomplished. The restoration of venous circulation was omitted. Cooling of tissues to prolong viability while they were without circulation was not done.

Steps were taken to insure that circumstances would favor success at the next opportunity of limb reimplantation. A team was formed to include surgeons experienced in vascular and orthopedic procedures. Several bottles of lactated Ringer's solution were stored in the operating room refrigerator with instructions for adding heparin, antibiotics and low molecular weight dextrose to make up a suitable solution for perfusing the limb by gravity flow. Instructions for management of the patient and the amputated limb were issued to rescue teams, to operating room personnel, and to emergency room personnel. Shortly after this the following incident occurred.

Report of Case

A skilled mechanic injured in a machinery explosion was brought to the Milwaukee County Hospital 30 minutes after the injury. The left hand had been severed at the distal radius level. The hand was not brought with the patient and had to be retrieved at the site of the accident.

One team of two surgeons cleaned the hand and perfused it with the prepared iced solution and placed a rod in the ulna and a plate on the radius. During evaluation of the patient's other injuries (including a depressed skull fracture) their definitive treatment was delayed. A second team debrided the arm stump. Bony fixation was accomplished without delay. Shortening of the bones permitted excision of ½ inch of each end of the radial artery before anastomosis. The artery was opened as soon as the vein anastomosis was completed, 4½ hours after surgery. The ulnar artery was sutured to a large branch on the ulnar aspect of the wrist. Nerves were identified and tagged. The wrist tendons were sutured and the skin closed.

When good appearance of the hand did not persist, a variety of supportive measures were instituted to overcome vessel spasm. Fourteen hours later the hyperbaric chamber was used for two hours at three atmospheres of pressure. Improvement of the hand was definite. In the next 36 hours five more similar treatments of 30 minutes each were given.

Sixty hours after reattachment of the hand a fluorescein test revealed no circulation and re-amputation was done.

Method of Study

The vessels were excised at the anastomoses and prepared for microscopic sections. The radial artery just below the anastomosis was hemorrhagic and revealed fragments of bone and cotton fibre imbedded in its wall, not detected at the time of surgery. X-ray examination after hypaque injection showed good filling of the deep volar arch and small vessels to the thumb and index finger. A puddle of dye in the palm of the hand was due to extravasation from the ulnar artery. Dissection showed that the distal portion of the ulnar artery was retraced into the palm and that the ulnar artery had been sutured to a branch of the palmar end of the ulnar artery. Failure was blamed on thrombosis occurring at the site of the unrecognized foreign bodies and the injury to the radial artery.

Continued

Discussion: Dr. Edward J. Beattie, Jr. of Chicago reported a similar case in which the hand was saved after being severed in a paper cutting machine. The hand was flushed with cold heparinized saline. The bones were pinned and the radial artery anastomosed. The veins presented the greatest difficulty. A thorough and careful attempt to get as much venous return as possible to avoid excessive edema of the hand is important. The hand of their patient had sufficient lymphedema to necessitate multiple pie-crust incisions. Because there was good retrograde flow of blood from the cut-off end of the ulnar artery it was not anastomosed. This may have been a good procedure as it gave less venous run-off and less edema. Because of the edema this patient did lose his little finger and fifth metacarpal.

In their case other hand structures such as nerves and tendons were not sutured. Dr. Beattie's impression is that these tissues should be sutured together at the time of the original surgery, as they found later repair was extremely difficult because of marked retraction. In their experience with this patient, the lymphatics regenerated rapidly. Experimentally in dogs they regenerate in about seven to eight days. Dr. Beattie thinks this was the first attempt at such an operation. This patient has a hand, not a perfect one, but one with a pincer-like grip, and when last seen sensation had returned to the terminal joints of the fingers.

Comment: It would seem to be no great effort to accept the recommendations drawn up by the Milwaukee Hospital committee. Where trauma care is given, a team made up of surgeons trained in the surgery of trauma and of blood vessels could be available. Cold solutions of lactated Ringer's solution with anticoagulants and antibiotics should be available for prompt perfusing. Pressure by gravity should not be exceeded. Instructions should be given to emergency room personnel, ambulance attendants, and others regarding care of the patient and of the amputated member. If organs can be successfully transplanted, perhaps extremities may also be transplanted and be more functional than a traumatized replantation.

PANCREATITIS IN CHILDREN

Pancreatitis was encountered in 18 hospitalized children. The diagnosis was established clinically in four children and at postmortem examination in 14. Clinical findings, associated disease, laboratory data, and postmortem findings are described in the 14 patients who died and four who survived. Steroid administration, congenital anomalies, mumps, intestinal obstruction postoperatively, malnutrition, and infection were factors found to be of etiological importance in the development of pancreatitis. An analysis of factors affecting mortality indicates that hepatic and renal dysfunction augur a fatal prognosis.

Book Reviews

Books are those faithful mirrors that reflect to our mind the minds of sages and heroes. — Gibbon

RYPINS' MEDICAL LICENSURE EXAMINATIONS — **Arthur W. Wright, M.D., 10th Edition. J. B. Lippincott Company, Philadelphia, 10th Edition, Copyright 1965, 817 pages.**

This book was originally published in 1933, has been periodically revised and brought up-to-date, and is now in its 10th edition. Its primary purpose is to present a review of the major fields in basic science and clinical fields for the use of the candidate taking state license medical examinations. The text is divided into two parts, Part One, Basic Sciences, including sections on Anatomy, Physiology, Biochemistry, General Microbiology, Pathology and Pharmacology; Part Two, Clinical Sciences, including Surgery, Internal Medicine, Obstetrics and Gynecology, Preventive Medicine and Public Health, and Psychiatry. Each section consists of short, concise discussions of factual material in the particular field, followed at the end of each section by a series of questions designed to test the knowledge of the reader based on the text material presented. Theoretical and practical material are both presented. The clinical sections contain clinical findings, diagnosis, and treatment; and where applicable, basic pathophysiology is also included. A separate section is presented describing and outlining the types of examinations held by the national boards and various state boards, and also some discussion in regard to the preparation and policy relating to the examinations.

In general the book is extremely comprehensive, presenting a wide scope of material, yet eliminating all but the most essential information likely to be asked for in examinations. The text is clearly written by experts in the field. It not only concentrates on important material but also serves as an easily usable broad reference text. A separate section on Pediatrics is not included, although Pediatric Surgery is covered in the Surgery section and much of Pediatric Medicine can be found in the section on Internal Medicine. Tables and charts are used where they help clarify the text; no photographic or illustrative material is otherwise included.

The material is clearly and well presented and in my opinion is an excellent general preparation for the taking of not only state board examinations but any other examination covering wide areas of medicine and basic science. The book is also an excellent reference source with quickly and readily accessible information. Certainly anybody planning to take basic science or state board examinations would be well advised to read this book.

VITREORETINAL PATHOLOGY AND SURGERY IN RETINAL DETACHMENT — **Paul A. Cibis, M.D., St. Louis. C. V. Mosby Co. 1965. Illustrated, 293 pages, index, references, Price $20.00.**

The author, now deceased, has presented his experiences in the fast developing field of modern surgery of retinal detachment. The volume is divided into sections dealing with anatomy and physiology, including experimental observations; the various disease states and syndromes; and finally surgical techniques. The author pioneered in a number of newer techniques including vitreous surgery using the silicone liquids. It is indeed fortunate for students of this subject that Dr. Cibis was able to record so lucidly his experiences in the field before his untimely death.

CURRENT MEDICAL TERMINOLOGY — **Third Edition. Edited by Burgess L. Gordon. Published by American Medical Association. Chicago, 1966. 969 pp. Price $4.00.**

Current Medical Terminology is advertised as a reference system for the selection of preferred medical terms and synonyms . . . convenient, current, and timely. It is obviously timely and current, but to describe it as convenient abuses the word. The book is written in computer language: All caps; # is a colon; a small square, a semicolon. This is a step in the direction of computer medicine. A key word, a symptom, a sign, a laboratory reaction will set the wheels (or rather the magnetic tape) in motion and the diagnostic possibilities will appear. Thus in the key word section under "Jaundice" there are 100 entries followed by 100 numbers. One needs only to refer to another section, look up the numbers and find 100 diagnostic possibilities. With a computer available, obviously the whole process would be complete in a few milliseconds. Lacking that gadget, working from section to section, the patient would die before the task was completed. The reaction of this reviewer # THIS MARRIAGE OF MEDICINE TO THE COMPUTER HAS SPAWNED # A BASTARD.

LONG BEFORE Broders defined, described, and illustrated the microscopic picture of carcinoma in situ in 1932, gynecologists and pathologists occasionally had observed worrisome lesions of this type in the uterine cervix. The lesions were not termed "cancer" because they lacked the invasive qualities which, at that time, were considered necessary before a diagnosis of malignancy could be justified.

Cancers of the cervix were supposed to be at least visible, if not palpable. Accordingly, in the period 1932 through 1946 Broders and his associates made biopsies of every type of uterine cervical abnormality that they could see, and they discovered 32 examples of in-situ carcinoma of the cervix among the thousands of lesions sampled. For every in-situ cancer found, they saw and treated perhaps more than a hundred clinical cancers of the uterine cervix. If any relationship existed between in-situ and overt carcinomas, it was not apparent on the basis of their methods of study.

About that time, the late Dr. George Papanicolaou, while employing a special stain for studying exfoliated cells in vaginal secretions from patients with infertility problems, began to find dark-staining elements which he could not name. His careful observation and follow-up studies led him to the discovery that these abnormal cells had their sources in the lesions which Broders had described. The selfsame elements appeared also to be cast off from clinical cancers of the cervix. Evidence suggested that in-situ lesions were, in fact, early cancers.

A stampede followed. Every conceivable body orifice was scrubbed, scraped, washed, brushed, siphoned, and massaged for its maximal yield of cells, some of which might be malignant. Studies were conducted in which the efficiency of the smear technique was compared with that of biopsy. The problems of "false positive" smears were cussed and discussed. Theoretic and actual relationships between in-situ cancers and clinical cancers were expressed—statistically and otherwise. Terms like "precancer" were resurrected to explain the occurrence of suspicious smears of dubious cellular parentage. From a welter of reports on these and allied aspects of the problems posed by smears, two practical observations emerged: (1) smears are extremely valuable in detecting pulmonary and uterine cancer, and (2) smears can be successfully employed in the discovery of nearly 100% of cervical cancer in the in-situ stage. In our own experience, the yield when the smear is used is perhaps 50 times that obtained by using the method of selective biopsy.

How To Make a Smear

In gynecology, *exfoliative cytology* has its greatest usefulness in the detection of preclinical, asymptomatic carcinomas of the uterine cervix. These invisible lesions nearly always begin in the squamous epithelium at its junction with the glandular epithelium of the endocervix. This zone, usually in the region of the cervical external os, can be visualized, and scrapings can be taken directly. The Ayre wooden spatula has two prongs, shaped so that one prong can be inserted into the os while the other scrapes cellular material from the entire circumference of the adjacent exocervix. Perhaps less efficient is an ordinary tongue blade, because of its shape, or a cotton applicator stick, because it absorbs some of the cell-containing secretions.

A combination of endocervical aspiration material and cervical scrapings can be placed on one slide. Although some physicians prepare smears from one patient on several slides, one well-prepared smear is probably adequate. To facilitate examination, the material must be smeared evenly on the slide in one or two strokes. Excessive smearing of the material distorts cells and allows drying of cells before fixation. Immediate immersion in fixative is mandatory, since drying destroys cytologic details. Ethanol (95%) or several other solutions of alcohol or alcohol and ether produce satisfactory fixation.

Procedure when Smear is Positive

Most pathologists report the diagnosis of a smear in categories: classes 1 through 5 which indicate normal, slightly suspicious, suspicious, very suspicious, or malignant cells present, respectively. When there is no clinical evidence of cancer, a class 3 smear report from our laboratory indicates a 50% chance of cancer actually being present, and a class 5 report indicates a nearly 100% chance. Almost all of these preclinical cancers are in-situ lesions of the cervix.

Tissue must be procured from the entire circumference of the junctional zone. Instrumentation, including even the taking of office biopsies, may destroy the histologic evidence of early lesions which often involve only a fraction of the circumference. Accordingly, endocervical and endometrial scrapings should be procured only after the cone is taken. Good rapid-frozen technique allows immediate analysis of these specimens so that any indicated definitive therapy can be accomplished promptly.

The Gynecologist Looks at the Pap Smear

The value of the vaginal (Papanicolaou) smear as an aid in the detection of cancer of the female reproductive tract in general and the uterine cervix in particular has been proved beyond doubt. In the clinician's office, it is most efficiently used for three purposes.

As a Screening Tool

The practicing physician uses the smear most frequently as a general evaluation procedure in the asymptomatic gynecologic patient to complement the routine pelvic examination. This is done to detect exfoliated malignant cells of early nonvisible and nonsymptomatic cancer of the uterus. When an abnormal smear is reported under these circumstances, certain well-defined steps must be taken by the clinician. If the smear is suspicious, a repeat smear is always indicated with or without multiple cervical biopsies; if the smear is positive, multiple biopsies are mandatory. These biopsies can and should be taken in the office with punch-biopsy forceps; hospitalization is unnecessary. Bleeding is controlled if necessary by a vaginal pack or pressure on the bleeding point. If a diagnosis on which treatment can be based cannot be made from the tissue removed at biopsy, a cervical conization and curettage in the hospital, with the patient under anesthesia, is necessary before treatment is prescribed. The need for these surgical procedures emphasizes that *the smear is not a diagnosis* and identifies neither the origin nor the extent of the cancer.

As a Complement to Biopsy

When pelvic findings suggest the possibility of cervical malignancy, both a biopsy and a smear should be taken. The accuracy of the two techniques combined is greater in the detection of cervical malignancy than is either alone. If intrauterine malignant disease is suspected, a smear should also be taken and curettage performed. Conization is indicated if biopsies are inconclusive of the presence or absence of malignancy in the cervix.

As a Follow-up for Treated Carcinoma

A vaginal smear is essential as a routine in the evaluation at each follow-up examination of women treated surgically or radiologically for cervical cancer. A smear will detect abnormal cells prior to gross tissue change visible to the naked eye. These smears detect only local recurrence and not metastases elsewhere in the body. Benign cells on the smear from an irradiated patient may show bizarre changes secondary to irradiation, years after completion of therapy. Under no circumstances should the patient be subjected to further treatment on the basis of an abnormal smear unless there is tissue evidence of recurrent cancer.

Before a smear is regarded as a false-positive one, all procedures available for the detection of the occult cancer must be exhausted. Carcinoma of the fallopian tube and the ovary must be seriously considered as a possibility if the abnormal smear persists and there is no other explanation. Infections may be responsible for the false-suspicious or false-positive smears; in these cases, the smears revert to negative after the infection subsides.

False-negative smears have been reported in up to 10% of cervical cancers. For this reason, a single negative smear should not be accepted by the physician or patient as necessarily indicative of the absence of malignant disease if a suspicious lesion or symptoms are present.

Radiotherapy in Patient with Positive Pap Smear

In the young patient with a positive smear and carcinoma *in situ,* total hysterectomy and intracavitary radium therapy are both acceptable forms of treatment. Both can be expected to give equally good results. If the patient is in the child-bearing age and still wishes to have children, therapy can be deferred as long as continual careful observation is provided. There is an alternative to such a policy: the cervix can be treated, with an intravaginal cone, with kilovoltage techniques, coupled with surgical replacement of the ovaries laterally to ensure minimal radiation to these organs. Delivery of 6,000 rads in five to six weeks to the cervix alone with this technique permits high-dose radiotherapy to the involved area while minimizing the dose to all other pelvic organs and structures.

The patient with a positive smear who, on biopsy, is proved to have invasive carcinoma of the cervix requires treatment appropriate for the lesion as staged according to the League of Nations classification. With few exceptions, radiotherapy is the method of choice.

Consensus of Discussion

In the question-and-answer period which ensued, certain points of agreement and disagreement were presented.

It was the consensus of the essayists that, when unchecked, in-situ carcinoma of the cervix progressed to the clinical phase of the disease. Several agreed with the concept of Stewart that clinical cervical carcinoma could arise in no other way. The calculated average duration of the in-situ phase was perhaps in excess of 10 or 15 years. In certain regions with stable populations, screening programs with the smear technique have resulted in the discovery of many in-situ carcinomas of the cervix. In these same regions the incidence of invasive cervical carcinoma has recently shown a sharp decrease.

It was unanimously agreed that changes in the cervix due to pregnancy never imitate those due to carcinoma in situ and that a positive smear in a pregnant woman is of great significance. Opinions differed as to how one should proceed in establishing the tissue diagnosis in these cases, with some insisting on conization and others, on four-quadrant biopsies. With the diagnosis of infiltrating carcinoma for practical purposes excluded by biopsy, the urgency for conization was argued against the policy of watching the patient until after delivery. It was pointed out that the trauma of vaginal delivery may sometimes destroy a small focus of in-situ carcinoma of the cervix.

The young woman with one of these "in-

Continued

visible" cancers of the cervix can often be treated by simple conization. There is some morbidity associated with the operation and the patient must return periodically for further smear studies. However, approximately 50% of in-situ squamous cell carcinomas extend for variable distances into the endocervix. In these instances, residual carcinoma may remain following anything but a deep conization. Postoperative smears, fortunately, lead to discovery of these residua, and additional, more radical treatment will still effect a cure.

Finally, it was again pointed out that a screening program for the detection of early and curable cancer of the cervix by the smear technique is a team project. Reading the smears is a time-consuming job which requires very special training. Improperly made smears should be reported as unsatisfactory with a "repeat" requested. The reports should be "negative," "suspicious," or "positive." The pathologist should establish his criteria so that the first and last categories are truly meaningful; the middle category should be kept to a reasonable minimum. Should a large proportion (more than 70%) of patients in the "suspicious" category prove not to have carcinoma, the pathologist is causing the patient and the gynecologist undue concern. On the gynecologist's part, it is mandatory that the search for the lesion productive of a positive or suspicious smear be meticulous so that the evidence is not destroyed by the injudicious use of cautery following biopsy. It has been shown that vigorous scrubbing of the cervix preparatory to taking a cone can practically denude the cervix at a site showing in-situ carcinoma.

The Tobacco Tyrant*

Allbut mentions cardiac irregularity and even delirium cordis. Palpitation is common, especially among the young smokers. He says that smoking may cause violent angina which is distinguished from true angina pectoris by "the excessive violence and length of the attacks." He also says that blood pressure rises during smoking and falls below normal after cessation.

Wilson describes two cases of unusually severe anginoid pain which ceased after smoking was discontinued.

Kulbs describes arrhythmia, extrasystoles, and tachycardias, especially in the young. After the age of 50 there may arise symptoms of angina and aortalgia. In the interval between the attacks, bradycardia is more common than tachycardia.

John found an increase in both systolic and diastolic pressures during smoking, which was followed by a fall, lasting two hours, on cessation.

Pozzi & Clerc studied the effects of nicotin on cardiac rhythm in animals. They divided these into an initial bradycardia and a later tachycardia phase. In the former, they occasionally noted auricular arrest with ventricular arrhythmia, and less frequently auricular fibrillation. With tachycardia they observed lessened auriculo-ventricular dissociation.

To be continued next issue.

George Washington: His Death and His Doctors

> *"The comparison of what we can do with what we are expected to do is often mortifying enough. But it cannot be helped. People are free to expect what they like; while we cannot do more than can be done."*
>
> *Peter Latham, M.D.*
> *Lectures in Clinical Medicine, 1836*

ON THE EVENING of December 12, 1799, George Washington complained of a cold. Two days later he was dead. The American public, accustomed to the image of Washington as a man of health and vigor, received the news with stunned disbelief. This emotion soon turned to angry questioning of the treatment given by his three physicians. The public's attitude is reflected in a historian's statement: "There can scarcely be a doubt that the treatment of his last illness by his doctors was a little less than murder."[1]

This paper defends Washington's doctors and sets forth the argument that their actions were in keeping with the best medical practice of the times.

Sources

Two eyewitness reports of Washington's death exist. One was recorded in a personal diary by his secretary, Colonel Tobias Lear; the other was a newspaper account in the *Alexandria Times* and was written by two of his three physicians. Both were set down within five days of his death, and they differ little in detail. The state of Washington's health before his fatal illness has been gathered from his diaries and from his biographers. My information about medicine in the 18th century has been collected from dark corners which will be cited in the text. Lastly, I have been aided in interpretation of the events of Washington's final illness by two accounts of the subject.[2,3]

Washington's Health Before His Final Illness

George Washington was no stranger to disease or doctors. He was plagued by a series of illnesses, which started at the age of 16, when he had a bout of "ague* and fever, which I have had to extremity."[4] Three years later, while accompanying his consumptive brother, Lawrence, on a trip to Barbados, he was "strongly attacked with the smallpox."[5] He was nursed back to health, and contrary to popular belief, the disease left only a few insignificant scars on his nose — not a pockmarked face.[6]

After Washington's return to Virginia, he suffered a "violent attack of pleurisy which reduced me very low."[7] He feared that he had contracted his brother's tuberculosis, but his worry proved groundless. In 1755, he joined General Braddock of the British Army for a wilderness campaign against the French and Indians, but he was unable to march because of a four-day illness punctuated by waves of fever. His disease, he tells us, "was relieved by the General's ordering a physician to give me Dr. James powder** one of the most excellent medicines in the world."[7]

The fever returned in 1757 and was complicated by "bloody flux"-dysentery.[8] His physician, Dr. James Craik, an Edinburgh graduate who was to attend him in his fatal illness, advised him to retire from the army. He returned to Mount Vernon, but his symptoms persisted, and he wrote: "At certain periods, I have been reduced to great extremity and have much reason to apprehend an approaching decay. . . ."[7] Washington was morbidly pessimistic about all his

*Ague, according to the *Oxford Universal Dictionary*, is a word which originally denoted an acute fever, but subsequently came to mean the paroxysmal fevers of malaria.

**James powder was a mixture of antimonious oxide and calcium phosphate which induced sweating.

illnesses — not an unrealistic attitude in an age in which the life expectancy was less than 40.

A febrile illness in 1761 started with a "violent cold" and lasted for seven to eight months. After he recovered he ventured the dark opinion: "I was very near my last gasp . . . I once thought the grim King would overcome my best efforts and that I must sink in spite of a noble strength."[7] In 1768 he experienced another bout of dysentery, and a Dr. Rummey stayed with him for two evenings. He seems to have rallied nicely, for in a diary entry entitled "Where and How My Time was Spent," written shortly after his illness, he says that he had hunted foxes for 49 days, went to church for 15 days, paid many visits, attended two balls, three plays, one horse race; hunted ducks and played a quantity of cards.[5]

Washington had no serious illnesses during the nine years of the Revolutionary War. After the war in 1786, he had another attack of ague and fever which was relieved by Cinchona bark* prescribed by Dr. Craik.[2] During his presidency, which lasted from 1788 to 1796, Washington had three illnesses. The first occurred shortly after he assumed office and was a carbuncle on his left hip which incapacitated him for six weeks. He was treated by Samuel Bard, a well-known New York practitioner, who in 1771 had written a classical paper on "Angina Suffocativa."[9] In 1790, Washington had a "violent affection of the lungs, the cough, the pain in my breast, shortness of breath."[5] The last illness of his presidency occurred in 1793. Thomas Jefferson wrote to James Madison: "The president is not well; little lingering fevers have been hanging about him for a week or ten days and affecting his looks most remarkably." But Washington regained his strength, and his fever disappeared after a vacation at Newport, Rhode Island.

Washington's Last Years

Washington retired to Mount Vernon in March of 1797. His estates had been neglected during his eight years as president, and he was anxious to resume the duties of a gentleman farmer. He was 65 years old and was still a tall and sturdy figure who daily rode 15 miles around his estates. He weighed over 200 pounds and stood six foot three inches. When he was not supervising his estates, Washington enjoyed convivial gatherings over well-filled glasses of Madeira or hunting for canvasback ducks and foxes.

Washington's decision not to run for a third term was partially dictated by the infirmities of age. His hearing had become increasingly bad — possibly because of his previous treatment with Cinchona bark. He had worn glasses since 1780, and his ill fitting primitive dentures caused him torment and gave him the snaffle-mouth look which Gilbert Stuart had captured in his 1796 portrait of Washington — a picture immortalized on the dollar bill.

Washington's health was good during his retirement except for two febrile illnesses. In August of 1798, he wrote of a sickness which ". . . commenced with a fever on the 19th and lasted until the 24th which left me debilitated."[7] Later that year, he commented on "debilitated health occasioned by a fever which deprived me of 20 pounds of weight."[7] His diary for the remainder of 1798 and for 1799 indicated a restoration of health.

Last Illness

On Thursday, December 12, Washington spent several hours on horseback, riding about and giving directions to his overseers. The weather was bad. Snow, mixed with rain and sleet, drenched Washington. When he returned home, Tobias Lear observed that his neck was wet and that snow was lodged in his hair. On Friday, Washington did not venture out in the morning because of a cold and severe sore throat, but he stepped out onto his front lawn in the afternoon to mark trees to be cut. He spent the evening reading and talking with his family. Because of his increasing hoarseness, Lear suggested he take something for his cold. His reply was "No, you know I never take anything for a cold. Let it go as it came."[2]

---

*Cinchona bark was named by Linnaeus in 1742 after the Countess of Chincon, who, when vice-queen of Peru, was cured of fever by Peruvian bark, and afterwards brought a supply of it into Spain. In 1800, quinine was prepared from Cinchona bark.

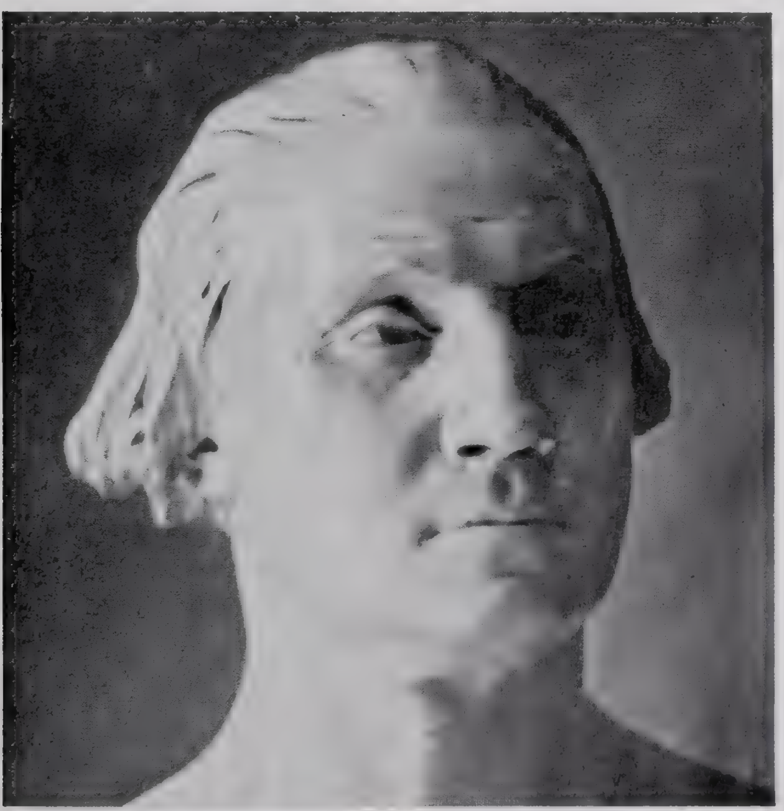
During the night he became rapidly worse with a high fever and pain in the throat. He developed difficulty swallowing with rapid respirations, and he was barely able to speak. At seven in the morning, Mrs. Washington called for Tobias Lear. He was shocked by Washington's appearance. According to Lear's diary: "A mixture of molasses, vinegar and butter was given, but he could not swallow a drop, and when he attempted, he appeared to be distressed, convulsive and almost suffocated."[2]

At Washington's request, Rawlins, an overseer, was sent for, and a pint of blood was taken without relief. Lear then applied sol volatile to his neck, and the patient complained of a tender neck. Because of his worsening condition, Lear dispatched his own servant for Washington's old friend, Dr. Craik who lived nine miles away in Alexandria. Shortly thereafter messengers were sent to summon Doctors Gustavus Brown and Doctor Elisha Dick.

The Doctors

Dr. James Craik arrived at Mount Vernon at about eleven o'clock in the morning. He was two to three years Washington's elder and had been his physician and social companion for at least 35 years. Dr. Craik was a Scotsman and a graduate of Edinburgh — a school which supplied America with 117 M.D.s before 1800.[3] He made a diagnosis of "inflammatory quinsy" and applied a blister of canthrarides to the throat, and did a second bleeding. Understandably, he was anxious for consultation, and he awaited the arrival of the other physicians. At 3 o'clock, Doctor Dick came, and Doctor Brown soon after.

Dr. Dick was 37 years old and a graduate of the University of Pennsylvania —



GEORGE WASHINGTON BY JEAN ANTIONE HOUDON (detail). This version of Houdon's 1784 bust belonged to Thomas Jefferson. It presents the hero vividly as a virile athletic man. Courtesy of the Boston Athenaeum. Photograph by H. H. Arnason.

Continued

founded in 1765. He had served his apprenticeship under Dr. Benjamin Rush and Dr. William Shippen — probably the two most famous physicians of America. He suggested a tracheostomy and cessation of further bleeding. Tracheostomy had not yet been performed in the colonies, and they elected not to undertake the operation on their illustrious patient. By the time Dr. Brown, another Edinburgh graduate, arrived, Washington could swallow, and the three physicians decided on symptomatic treatment. They administered a dose of calomel and tartar emetic.

Washington, sensing the end was near, asked his wife to bring him his wills. At 5 o'clock p.m. he sat up in a chair for one-half hour. He was obviously in great pain and had difficulty breathing. He never lapsed in an unconsciousness, but his breathing grew "imperfect." He expired between 10 and 11 p.m. on December 14 — 17 days before the dawn of the 19th century.

Statement to the Press

Doctors Craik and Dick submitted this statement to the *Alexandria Times* where it was published on December 19, 1977. It was subsequently reprinted in the *Medical Reposition,* founded in 1797, and the first medical journal of the colonies.

> "Presuming that some account of the late illness and death of General Washington will be generally interesting, and particularly so to the professors and practitioners of medicine throughout America, we request you to publish the following statement.
>
> Some time in the night of Friday, the 13th inst., having been exposed to rain on the preceding day, General Washington was attacked with an inflammatory affection of the upper part of the windpipe, called in technical language, cynanche trachealis. The disease commenced with a violent ague, accompanied with some pain in the upper and fore part of the throat, a sense of stricture in the same part, a cough, and a difficulty rather than painful deglutition, which were soon succeeded by fever and a quick and laborious respiration. The necessity of bloodletting suggesting itself to the General, he procured a bleeder in the neighborhood who took from the arm in the night, twelve or fourteen ounces of blood; he would not by any means be prevailed upon by the family to send for the attending physician till the following morning, who arrived at Mount Vernon at eleven o'clock on Saturday morning. Discovering the case to be highly alarming, and foreseeing the fatal tendency of the disease, two consulting physicians were immediately sent for, who arrived one at half past three and the other at four in the afternoon. In the interim were employed two copious bleedings; a blister was applied to the part affected, two moderate doses of calomel were given, an injection was administered which operated on the lower intestines, but all without any perceptible advantage, the respirations becoming still more difficult and distressing. Upon the arrival of the first of the consulting physicians, it was agreed as there were yet no signs of accumulation in the bronchial vessels of the lungs, to try the result of another bleeding, when about thirty two ounces were drawn, without the smallest apparent alleviation of the disease. Vapours of vinegar and water were frequently inhaled, ten grains of calomel were given succeeded by repeated doses of emetic tartar amounting in all to five or six grains, with no other effect than a copious discharge from the bowels. The powers of life seemed now manifestly yielding to the force of the disorder. Blisters were applied to the extremities, together with a cataplasm of bran and vinegar to the throat. Speaking, which was painful from the beginning, now became almost impracticable, respirations grew more and more contracted and imperfect, till half after eleven o'clock on Saturday night, when, retaining the full possession of his intellect, he expired without a struggle.
>
> He was fully impressed at the beginning of his complaint as well as through every succeeding stage of it, that its conclusion would be fatal, submitting to the several exertions made for his recovery, rather as a duty than from an expectation of their efficacy. He considered the operation of death upon his system as a coeval with the disease and several hours before his decease, after repeated efforts to be understood, succeeded in expressing a desire that he might be permitted to die without interruption.
>
> During the short period of his illness he economized his time in the arrangement of such few concerns as required his attention with the utmost serenity, and anticipated his approaching dissolution with every demonstration of that equanimity for which his whole life had been so uniformly and singularly conspicuous."
>
> James Craik
> Attending Physician
>
> Elisha C. Dick
> Consulting Physician
>
> The signature of Doctor Gustavus Brown, of Port Tobacco, who attended as consulting physician, on account of the remoteness of his residence from the place, has not been procured to the foregoing."

Treatment

Before any judgement can be made concerning Washington's treatment, the practice of medicine of the period must be understood. The Art outstripped the Science, and the classification of disease was a welter of conflicting systems. At one pole was William Cullen's doctrine of all diseases as nervous disorders and at the other was the dogma of John Brown, (1735-1788), who claimed that all diseases were due to an imbalance of stimuli. Brown, a coarse, disreputable man, classified all diseases as "sthenic" or "asthenic" and his treatment consisted of opium or alcohol — depending on the diagnosis. Morgagni's monumental treatise, *De Sedibus et Causis Morborum,* the bedrock of Pathological Anatomy, appeared in 1761; but it was in Latin and was probably unread by most American doctors.

At the time of Washington's death, auscultation, percussion and palpitation had not been developed and clinical instruments such as thermometers, blood pressure cuffs, stethoscopes, and laryngoscopes did not exist. The practice of clinical medicine rested on the theories of Boorhaave, (1668-1738), Sydenham (1624-89), and Cullen (1712-1790). Cullen was Craik's and Dick's professor at Edinburgh, and it is likely that they were students of his book, *First Lines in the Practice of Physic,* published in 1781.[10]

Cullen's book contained a chapter on Quinsy or Cynanche Trachealis. The following excerpt demonstrates that Washington's physicians followed closely the recommended therapy of Cullen — a recognized authority. Of cynanche treachealis, he writes, "This name has been given to an inflammation of the glottis, larynx or upper part of the trachea, whether it affects a membrane of these parts or a muscle adjoining. It may arise first in these and continue to subsist in them alone, or it may come to affect these parts from the cynanche tonsillaris or maligna spreading into them.

In either case it has been a rare occurrence and a few instances of it have been marked and recorded by physicians. It is to be known by a peculiar croaking sound in the voice, by difficult respirations with a sense of straightening about the larynx, and by an attending pyrexia.

From the nature of these symptoms and from a dissection of the bodies of persons who have died of this disease, there is no doubt of its being of an inflammatory kind. It does not, however, always run a course of inflammation, but frequently produces such as obstruction of a passage of air as suffocates, and thereby proves suddenly fatal.

If we judge rightly of the nature of this disease, it will be obvious that a cure of it requires a most powerful remedy for the inflammation, to be employed upon the first appearance of symptoms. When a suffocation is threatened, whether any remedies can be employed to prevent it, we have not an experiment to determine.

As we suppose the disease to be an inflammatory affection, so we attempt a cure of it by the usual remedies of inflammation, and which for the most part we have found effectual. Bleeding, both topical and general, has often given almost immediate relief, and by bleeding repeatedly has entirely cured the disease. Blistering also near to the part affected, has been found useful. Upon a first attack of the disease vomiting immediately after bleeding seems to be of use, and sometimes removes the disease. In every stage of the disease, an antiphlogistic requirement is necessary, and particularly the frequent use of laxatives. Though we suppose that a spasm of the glottis is often fatal in this disease, we have not found antispasmodic remedies to be of any use."

If Washington's doctors consulted the book of another authority, Thomas Sydenham, they would have found this advice for treating quinsy: "Bleed plentifully in the arm, and let the inflamed parts be besmeared with honey of roses, well acidulated with spirit of vitriol, or spirit of sulphur; and soon after let a gargle be used, not in the common way, but quietly in the mouth till it grows warm, and then spit out. . . Next morning, unless the fever and difficulty be abated, bleeding must be repeated, and purging deferred until the subsequent day, otherwise a gentle purge may be given."[11]

Dr. Elisha Dick's suggestion to perform a tracheostomy was remarkable because, had Brown and Craik complied with his wish, it would have been the first done in America. Among the first to successfully execute the operation was John Andree, a London Surgeon, in 1782, and the account of the subject did not appear until 1812.

In 1833, Trousseau knew of 21 instances of tracheostomy with seven patients saved.[13] Washington's three physicians cannot be blamed for failing to carry through with a tracheostomy. By 1799, there were probably more failures than successes, and they

Continued

would have been condemned had their efforts failed. Tracheostomy was not accepted by the medical profession until Trousseau popularized it in 1833.

Differential Diagnosis

In retrospect, Washington's physician's diagnosis of "cynanche trachealis" appears to be correct. Cynanche was a term applied to all inflammation of the throat and neck. Quinsy, the original diagnosis made by Craik, was also a nonspecific term relating to the throat, and did not, as now, mean peritonsillar abscess.

Doctors of the 18th century had a different view of sore throats than modern physicians. Necrotizing throats were a common fatal complication of scarlet fever, and of such serious illnesses as small pox, typhus, typhoid, and diphtheria. To compound the diagnostic problem, patients were often jammed together in filthy wards, and mixed infections were the rule.

Throat infections occurred mostly in epidemics with a high mortality rate. It appears that Washington's sore throat was not a part of an epidemic. For this reason and because of his age, diphtheria and the scarlet fever localized to the throat probably can be dismissed from the differential — although diphtheria and scarlet fever did occur in adults in that era. W. H. Wells, an otolaryngologist, wrote in 1927 that inflammatory laryngitis, possibly secondary to streptococcal infection, was the most likely diagnosis.[2] R. Scott Stevenson, an English Physician, agrees with the original diagnosis of quinsy.[3] A peritonsillar abscess may well have dissected into soft tissue of the neck, surrounded the larynx, and produced obstruction and death. Whatever the precise diagnosis, Washington's physicians had nothing in their medical bags — except a scalpel — to cure him.

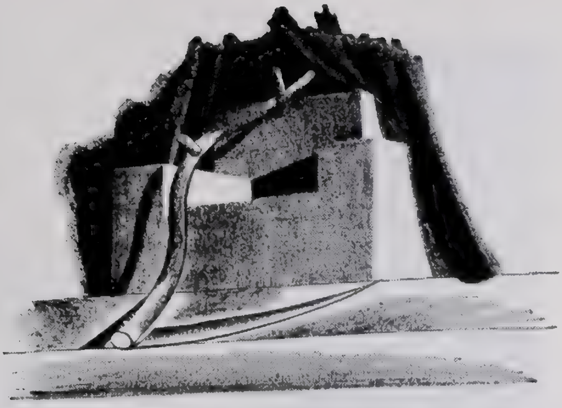
On Being a Patient

You cannot be a perfect doctor, till you have been a patient. You cannot be a perfect surgeon, till you have enjoyed in your own person some surgical experience. Enjoyed, I say, and stick to the word. Count the ways of enjoyment. To be the dear object of so much care and friendship, to be compassed about with hopes and prayers, is there no pleasure in that? To behave nicely, and nothing common do or mean, upon that memorable scene, but lie on the operating-table like Patience on a monument, is there no pleasure in that act of self-control? — Stephen Paget (1855-1926)



In Memoriam

Earth has no sorrow that heaven cannot heal. — Moore

MARSHALL I. HOWARD, M.D.

Dr. Marshall I. Howard, 66, former president of the Mankato Clinic, died March 27. Dr. Howard was born in Iowa, and received his medical degree at the University of Minnesota.

He was a member of the Minnesota Obstetrical and Gynecological Society, Minnesota State Medical Association, and American Medical Association. Dr. Howard was also a past president of the Blue Earth County Medical Society.

He is survived by his wife, a daughter, and a son, Dr. Michael Howard of Chicago.

NELLIE OLEA BARSNESS, M.D.

Dr. Nellie O. Barsness, 92, St. Paul physician and surgeon, died May 12. She was born in Polk County, Minnesota, and had lived in St. Paul sixty years.

Dr. Barsness was a past state health director of the Women's Christian Temperance Union, a member of the Ramsey County Medical Society, American Medical Association and a Life and 50 Club member of the Minnesota State Medical Association. She was also a member of the board of the American Medical Women's Association and the International Medical Women's Association.

She is survived by her son, Dr. Harry Simmonds of St. Paul.

GALEN H. ADKINS, M.D.

Dr. Galen H. Adkins, 57, medical director of the Cambridge State School and Hospital, died April 27, during the night of an apparent heart attack. He had served as superintendent of the Sandstone Institution from 1957 to 1959 after which time he became superintendent at Cambridge. In 1964 he was made medical director of that institution.

Born at Jetmore, Kansas, he received his medical degree at the University of Minnesota Medical School. Dr. Adkins was a member of the East Central Minnesota Medical Society, American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, five daughters and a son.

CARL R. BUTTURFF, M.D.

Dr. Carl R. Butturff, 82, physician at Freeborn since 1906, died April 1, after a long illness. A native of Marshall, he received his doctor of medicine at the University of Minnesota Medical School. Dr. Butturff practiced thirty-seven years in Freeborn before his retirement in 1949.

He was a member of the Freeborn County Medical Society, American Medical Association and a 50 Club and Life member of the Minnesota State Medical Association.

He is survived by his wife.

MALCOLM ROSSLAND JOHNSON, M.D.

Dr. Malcolm Johnson, 54, Minneapolis ophthalmologist, died May 21. Born in Willmar, Minnesota, he graduated from the University of Minnesota Medical School in 1935.

Dr. Johnson was a member of the American College of Surgeons, the American Academy of Ophthalmology and Otolaryngology, Hennepin County Medical Society, Minnesota State Medical Association and the American Medical Association. He was on the medical staffs of Swedish, Lutheran Deaconess and Veterans Hospitals.

He is survived by his wife, a son and a daughter.

ROBERT ZEMMERS, M.D.

Dr. Robert Zemmers, 67, Duluth anesthesiologist, died May 14 in a Duluth hospital. Born in Stalbe, Latvia, he came to the United States in 1948. He received his medical education at the University of Latvia Faculty of Medicine and served as a general practitioner in Valmieria, Latvia, becoming chief of the Department of Infectious Diseases at the Valmieria City Hospital before going to the United States.

He was a member of the St. Louis County Medical Society, Minnesota State Medical Association, Minnesota Society of Anesthesiologists, American Society of Anesthesiologists, and the American Medical Association.

He is survived by his wife and a son, Dr. Robert M. Zemmers of Minneapolis.

CHARLES E. MERKERT, M.D.

Dr. Charles E. Merkert, 69, a physician and surgeon in Minneapolis the past forty years, died May 18. Chief of staff of Lutheran Deaconess Hospital, Dr. Merkert was active in several public health associations.

He was a former chairman of the public health committee of the Hennepin County Medical Society, board member of the Minneapolis Surgical Society, member of the American Medical Association and an associate member of the Minnesota State Medical Association.

Born in St. Paul, Dr. Merkert received his medical degree at the University of Minnesota.

He is survived by his wife.

Physician's Diary

The true test of civilization is, not the census, nor the size of cities, nor the crops, but the kind of man that the country turns out. — Emerson

Dr. Gordon Hovde, Chisago City recently was appointed to the Green Acres Nursing Home Board.

* * *

Dr. Oliver H. Beahrs, head of a Mayo Clinic section of surgery, was elected a member of the board of trustees of the Mayo Foundation at its annual meeting.

* * *

Dr. Donald L. Carlson of Moorhead has been elected chief-of-staff at the St. Ansgar Hospital. **Dr. Richard H. Seifert** was elected vice-president, and **Dr. H. G. Rice**, the new secretary-treasurer.

* * *

Dr. Ellis S. Benson, professor of laboratory medicine and biochemistry in the University of Minnesota's College of Medical Sciences, has been named the new head of the laboratory medicine department.

* * *

Dr. Fred A. Lyon of Minneapolis has been installed as a fellow of the American College of Obstetricians and Gynecologists, and **Dr. Paul Hartig** of Minneapolis has been certified as a diplomate of the American Board of Urology.

* * *

Dr. H. E. Michelson of Minneapolis has been elected an honorary member of the Section of Dermatology of the Royal Society of Medicine of London.

* * *

Dr. Arthur M. Olsen of the Mayo Clinic has been reelected president of the Minnesota Tuberculosis and Health Association.

* * *

Dr. A. P. Goblirsch of Sleepy Eye was honored for forty years of service to that community. A plaque honoring him was presented during a dinner held in his honor.

* * *

Dr. Roger I. Lienke of Minneapolis has been elected to a membership in the American Academy of General Practice, and **Dr. Neil D. Nickerson** of Fairmont has been admitted to a full fellowship in the American College of Physicians.

Dr. Richard H. Decker, research associate in the Mayo Clinic section of biochemistry, received a five-year career development award from the National Institutes of Health, and **Dr. Leonard A. Lang**, Minneapolis obstetrician and gynecologist, received an alumni award from the pre-medicine and biological science students at the College of St. Thomas.

* * *

NEW LOCATIONS: **Dr. David S. Berkman**, medical staff physician at the Rochester State hospital, plans to open a private practice of medicine in Emily . . . **Dr. Timothy Nealy** opened a medical practice in Blooming Prairie . . . **Dr. William O. Reid** has joined the Rice Memorial Hospital in Willmar . . . **Dr. Elton Glenn Wing** will join **Dr. E. E. Keithahn** in the practice of medicine in Sleepy Eye . . . **Dr. Elizabeth Rieschl** of Jordon is to be associated with the New Prague Medical Clinic.

* * *

Dr. Robert A. Good, professor of pediatrics and microbiology at the University of Minnesota, received an honorary doctor of medicine degree from the University of Uppsala, Sweden.

* * *

Dr. Richard V. Ebert, professor and head of the department of medicine at the Medical School of the University of Arkansas, will head up the department of medicine in the University of Minnesota's College of Medical Sciences.

* * *

The March issue carried a statement that the Wyeth Pharmaceutical Company had given **Burtrum Schiele, M.D.**, professor in the department of Psychiatry of the University of Minnesota, an unrestricted grant for medical research. Dr. Schiele did receive the check; however, the grant was given jointly to **Dr. Richard Teeter**, Chief of Psychiatry at the St. Paul-Ramsey Hospital, and **Dr. James Janecek**, Chief of the Inpatient Service at the same hospital.

* * *

St. Luke's Hospital in St. Paul celebrated its 111th birthday, May 17. The first building was a small wooden structure near the capitol.

broad-spectrum performance above and beyond the activity of ordinary tetracyclines

DECLOMYCIN®

DEMETHYLCHLORTETRACYCLINE

Effective in a wide range of everyday infections—respiratory, urinary tract and others—in the young and aged—the acutely or chronically ill—when the offending organisms are tetracycline-sensitive.

Contraindication—History of hypersensitivity to demethylchlortetracycline.

Warning—In renal impairment, usual doses may lead to excessive systemic accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of discomfort.

Precautions and Side Effects—Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. Use of demethylchlortetracycline during tooth development (last trimester of pregnancy, neonatal period and early childhood) may cause discoloration of the teeth (yellow-grey-brownish). This effect occurs mostly during long-term use but has also been observed in short treatment courses. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment. Side reactions include glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and dermatitis. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Anaphylactoid reactions have been reported.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products.

Capsules: 150 mg; *Tablets:* film coated, 300 mg, 150 mg, and 75 mg of demethylchlortetracycline HCl.

LEDERLE LABORATORIES, A Division of American Cyanamid Company, Pearl River, New York

Life-saving words. Required by Congress to appear on all packages of cigarettes.

Unquestionably an important step forward in the dramatic battle to decrease the mortality and morbidity from cigarette smoking.

But in the nation's efforts to reduce death and disease related to cigarette smoking, the most significant influence—the key figure—is you, doctor. The advice of the physician in matters of health is more authoritative and persuasive than that of anyone else.

In the area of cigarettes and health, the importance of the physician's attitude and his *personal action* cannot be overemphasized. That he has indeed taken personal action is indicated by the impressive statistic showing that only 30% of the doctors in America are cigarette smokers today!

The American Cancer Society's concerted educational campaign on the hazards of cigarette smoking—plus government regulations—will be major factors in guiding each person's approach to this problem.

But in the final analysis, doctor, it is *your* words that your patients will heed. It is you who have the best chance of actually helping an individual to stop smoking or to prevent him from starting.

AMERICAN CANCER SOCIETY®

Excellent clinic one block from hospital. Salary with early partnership. Locum tenens also considered. Call collect 218-782-4725 or write Klefstad Clinic, Greenbush, Minnesota.

Bamadex® Sequels®

Contraindications: In hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised; especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of pre-existing symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dose—operation of motor vehicles, machinery or other activity requiring alertness should be avoided. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness.

Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia, the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor, and respiratory collapse.

Bamadex® Sequels®

d-amphetamine sulfate (15 mg.) and meprobamate (300 mg.)

Sustained Release Capsules

By providing combined anorexigenic-tranquilizing action, BAMADEX SEQUELS Capsules help your nonshrinking patients to establish new patterns of eating less. The amphetamine component suppresses the appetite, while the meprobamate helps allay nervousness and tension. And for most patients, the *sustained* release of the active ingredients makes possible convenient one-capsule-a-day dosage.

Minnesota Medicine at a Glance

Exanthem: Echovirus Infection — Wedemeyer et al. Page 1057

In recent years there have been numerous reports of rashes associated with diseases caused by the Echovirus and Coxsackie virus. A case is reported of a one-year-old girl with a febrile illness of three weeks duration, who, with the onset of her illness, developed a fine discrete rash over her face. The rash progressed distally and became a discrete red maculopapular eruption, especially on the distal upper arms and the anterior trunk and legs, and was described as similar in appearance to erythema infectiosum or erythema multiforme. Other findings were: mild generalized lymphadenopathy, anorexia, mild diarrhea, lethargy and mild ataxia. Virological studies demonstrated presence in the stool of Echovirus type 18, and acute and convalescent sera from the patient revealed a fourfold rise in antibody titer to Echovirus type 18.

This is the second case of an exanthematous disease reported in association with Echovirus type 18 infection and indicates the value of virologic study, particularly in atypical exanthematous diseases.

Primary Hyperparathyroidism — Winter et al. Page 1061

Despite a continuing gain in knowledge concerning calcium and phosphorus metabolism, primary hyperparathyroidism persists in presenting some problems in diagnosis. Some of the unusual and occasionally bizarre symptoms of hyperparathyroidism are enumerated in this study of 24 patients. In a case report one patient who apparently had symptoms for a period of 21 years was finally proven to have a chief cell adenoma of the parathyroid. No doubt because of the kidney damage that had been produced over this long period of time, he died from the sequelae of this disease which had not been previously recognized.

Sarcoidosis with Chylothorax — Aberg et al. Page 1065

Sarcoidosis continues to remain ideologically an obscure problem, with an ever increasing variety of clinical manifestations.

The close follow-up of a case reported by Aberg et al. reveals some interesting and unusual findings well worth more extensive scrutiny.

Treatment of Acute Myeloid Leukemia — Kennedy et al. Page 1071

A combined chemotherapeutic regime consisting of 6-mercaptopurine (2.5 mg. per kilo. per day by mouth for five days) and cyclophosphamide (40 mg. per kilo. intravenously in a single dose on the sixth day) was administered to ten patients with leukemia. Two of the patients had had chronic granulocytic leukemia and were in an acute transitional phase. Three patients were classified as having subacute granulocytic leukemia, and four patients, acute granulocytic leukemia. One patient had a myeloproliferative syndrome. An increase in the hemoglobin and platelets was noted in three patients and all had reductions of leukocytes and myeloblasts. Androgens were also used in two of the patients, resulting in an increase of the hemoglobin. Possible metabolic basis for the apparent synergism leaves an interesting thought for further speculation.

Pulmonary Nocardiosis — Yue et al. Page 1077

Nocardiosis is a severe but uncommon fungus disease. Early diagnosis and treatment are necessary for a favorable outcome. Two cases seen at the Glen Lake Sanatorium are presented.

Nocardiosis is most commonly introduced to the body via the respiratory tract. It can proceed in a variety of ways, producing infection, suppuration, and abscess. It frequently resembles very closely a wide variety of other infectious diseases.

Erythroblastosis Fetalis — Adcock Page 1081

The genotype of the father and the obstetrical history, prenatal course and antibody titer levels of the Rh sensitized mother do not provide sufficient information to always determine the severity of erythroblastosis fetalis prior to birth. The study of amniotic fluid bilirubin pigments, however, measures the degree of affectation of the intrauterine fetus and guides its treatment. Intrauterine transfusion may allow maturity of the fetus, and properly timed premature delivery with exchange transfusion can salvage a large proportion of the infants.

Obstructive Airway Disease — Dines Page 1089

A case of emphysema with severe disability and considerable aberration of pulmonary function as determined by a battery of tests was actively treated for one year with high fluid intake, breathing exercises, expectorants, nebulization, bronchodilation, and antibiotics. Significant symptomatic and laboratory improvement occurred.

Agammaglobulinemia — Neuro-Pediatrics Conference Page 1123

Infants suffering from agammaglobulinemia are subject to recurrent bacterial infection caused by primary pyogenic organisms and a variety of other diseases. The definitive diagnosis is dependent upon immunologic tests. There are many other procedures which, if positive, lead to a presumptive diagnosis.

The mental retardation which was observed in this child no doubt resulted from the residue of a meningitis which developed when he was five years old. After this the child made no appreciable advance in mental status, and the problem of further education and a full evaluation of this child's condition is detailed in the Neuro-Pediatrics Conference.

Hypertensive Crisis and Parnate — Crosson Page 1155

Parnate is one of the many monoamine oxidase inhibitors used for the treatment of depression and hypertension, but in prescribing it one must keep in mind the possibility of some side effects in certain individuals who have a metabolism that cannot completely metabolize the tyramine in certain types of cheese.

This is well illustrated in the case report of a woman who was taking tranylcypromine and had for the first time eaten some Cheddar cheese.

There is a Moral Sense and there is an Immoral Sense. History shows us that the Moral Sense enables us to perceive morality and how to avoid it, and that the Immoral Sense enables us to perceive immorality and how to enjoy it. — Mark Twain

to help restore and stabilize the intestinal flora

LACTINEX®

TABLETS & GRANULES

for fever blisters and canker sores of herpetic origin

LACTINEX contains a standardized viable mixed culture of *Lactobacillus acidophilus* and *L. bulgaricus* with the naturally occurring metabolic products produced by these organisms.

LACTINEX was introduced to help restore the flora of the intestinal tract in infants and adults.[1,2,3,4]

LACTINEX has also been shown to be useful in the treatment of fever blisters and canker sores of herpetic origin.[5,6,7,8]

No untoward side effects have been reported to date.

Literature on indications and dosage available on request.

Winthrop announces
new
WinGel®

**ANTACID
TABLETS
AND LIQUID**

For peptic ulcer, gastric hyperacidity, gastritis

Each WinGel tablet or teaspoon (5 ml.) contains 410 mg. of combined, highly reactive, short polymer, aluminum and magnesium hydroxides **stabilized with hexitol.**

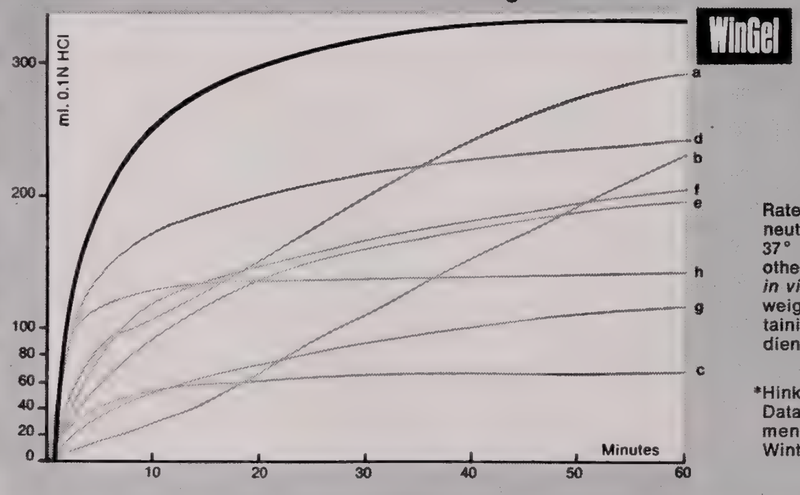
Neutralizes 300 times its active-ingredient weight in gastric acid for fast, long-lasting relief

Gastric or duodenal ulcer, acute or chronic gastritis, gastric hyperacidity...wherever there is "acid overflow" new WinGel can provide faster, longer, more complete neutralization.

In recent laboratory comparisons* with eight other leading antacids, new WinGel tablets not only neutralized more hydrochloric acid per active-ingredient weight, but neutralized it faster and longer than all other antacids tested.

Pleasant pink in color, WinGel is delicately mint flavored with a smooth-as-cream texture—qualities sure to please the patient on long-term therapy. New WinGel is also specially formulated to avoid constipation or diarrhea.

New WinGel neutralizes 300 times its active-ingredient weight in 0.1N hydrochloric acid—neutralizes more acid faster than other leading antacids



Rate of 0.1N hydrochloric acid neutralization at pH 3.5 and 37° with WinGel and eight other leading antacid tablets—*in vitro*. Samples equaled the weight of tablet material containing 1.0 Gm. active ingredients.*

*Hinkel, E. T., Jr. (New York): Data in the files of the Department of Medical Research, Winthrop Laboratories.

Dosage: Peptic ulcer or gastritis—from 2 to 4 teaspoons of WinGel liquid or 2 to 4 tablets chewed or allowed to dissolve in the mouth every two to four hours. **Gastric hyperacidity**—2 tablets or teaspoons about ½ to one hour after meals as needed; children from 7 to 14 years of age, 1 or 2 tablets or 1 or 2 teaspoons of liquid as needed.

How Supplied: Liquid in bottles of 8 fl. oz. and 1 pint. **Tablets** in cellophane strips, boxes of 50 and 100. (One teaspoon of WinGel liquid is equivalent to one WinGel tablet in acid-combining capacity.) WinGel, trademark reg. U.S. Pat. Off.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

DECLOMYCIN®

DEMETHYLCHLORTETRACYCLINE

Effective in a wide range of everyday infections—respiratory, urinary tract and others—in the young and aged—the acutely or chronically ill—when the offending organisms are tetracycline-sensitive.

Contraindication—History of hypersensitivity to demethylchlortetracycline. *Warning*—In renal impairment, usual doses may lead to excessive systemic accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. *Precautions and Side Effects*—Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. Use of demethylchlortetracycline during tooth development (last trimester of pregnancy, neonatal period and early childhood) may cause discoloration of the teeth (yellow-grey-brownish). This effect occurs mostly during long-term use but has also been observed in short treatment courses. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment. Side reactions include glossitis, stomatitis, proctitis, nausea, diarrhea, vaginitis and dermatitis. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Anaphylactoid reactions have been reported.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products.

Capsules: 150 mg; *Tablets:* film coated, 300 mg, 150 mg, and 75 mg of demethylchlortetracycline HCl.

President's Letter

T*he House of Delegates,* at the recent American Medical Association Meeting in Chicago, considered more resolutions, heard more discussion and met in more and longer sessions than at any other previous meeting in recent history.

As might be expected, most of the discussions revolved about some aspect of Medicare, with an increasing amount of attention being given, as the meeting continued, to the extraordinary, previously unrecognized potential for future changes in the practice of medicine which will follow state implementation of Title XIX.

The sheer volume of material considered and acted upon by the House necessarily left some gaps in the otherwise detailed reporting found in the American Medical Association News, gaps even more apparent in current reports from other news media. Consequently, physicians not in attendance at the session may miss, in some of the points under discussion, basic philosophy motivating House action.

When the Doctrine of Individual Responsibility as presented in the Report of the Council on Medical Service was later considered, together with resolutions on the same subject in reference committee, presented to and endorsed by the House as an acceptance of those principles, the report, the resolutions under consideration, the discussion before the reference committee and before the House could not be condensed, but only the House action reported as an official act.

The philosophy of the Committee on Medical Services as expressed in the report concerns a responsibility as well as a right of the practicing physician. The physician has a right to compensation for services he has provided, and the patient has a responsibility to compensate the physician. The physician has the responsibility of providing those needed services, and the patient has the right to expect those services from the physician of his choice, the physician being free to determine what method of compensation is equitable to the patient and to himself. Direct financial dealing with the patient has many advantages, but acceptance of compensation under other circumstances is neither inappropriate nor unethical. It is well to recall then that individual responsibility is not a unilateral doctrine applied only to the patient and to payment by the patient for provided services, but is a dual doctrine involving the physician as well.

The report of the Council on Medical Service reiterated the previous opinion expressed by the American Medical Association that prepaid health insurance is essential in preserving the private practice of medicine and requires not only the recognition of this fact by physicians but also close cooperation between physicians and the insurance industry, as well as physician freedom to cooperate to the fullest degree with any third party which merits that cooperation and support.

During the session of the House, while definitions of usual and customary fees were being considered, a communication from the Medical Advisory Committee was distributed announcing the receipt from Mr. Arthur Hess of proposed Regulation #5 and a draft

Phenergan Given During Labor

Not A Cause of Neonatal Jaundice*

R. A. DIAMOND, M.D.**
C. A. TIETZ, M.D.**
W. N. SPELLACY, M.D.**
Minneapolis, Minnesota

SEVERAL GROUPS of drugs are known to cause jaundice in some newborn infants. Many of the phenothiazine drugs can cause jaundice in adults by a cholestatic mechanism and can inhibit bilirubin conjugation *in vitro*. One phenothiazine drug, promethazine,† is widely used in obstetric anaesthesia. The purpose of this paper is to report the results of a double-blind study of neonatal jaundice and the use of promethazine in labor.

Methods

This study made use of 245 patients who were admitted to the University of Minnesota Hospitals between January 1, 1965, and November 1, 1965, in active labor. When labor was established, the patients were assigned to one of two drug groups according to a code of random numbers. Each patient was given one ml. of a solution intravenously and a sheet was completed with the clinical information. The two solutions were identified only by a number until the completion of the study, at which time they were identified as either Phenergan® (25 mgm./ml.) or saline as a control. The only other drugs used in combination with the above study drugs were meperidine, secobarbital and hydroxyzine. A previous study has shown that there is no alteration in neonatal bilirubin levels caused by any of these three drugs.[1] A direct Coombs test was done on a cord blood sample from each infant. Infants with a positive test were excluded from this study. Between the 30th and 66th hours of life a blood sample was obtained from all of the infants delivered to mothers in this study. The serum bilirubin was determined on these samples by the Ducci and Watson colorimetric method with bilirubin standardization adopted from Watson and Rogers.[2,3] The completed data sheets recorded the drug used, the length of time from drug injection to completed delivery, the infant birth weight, and the neonatal bilirubin level.

---

*Presented at the Minnesota State Obstetrical and Gynecological Society meeting, December 4, 1965, St. Paul, Minnesota.

**From the Department of Obstetrics and Gynecology, University of Minnesota Medical School, Minneapolis, Minnesota 55455.

†Promethazine was supplied as Phenergan® by the Wyeth Laboratories, Inc., Philadelphia, Pennsylvania.

Results

After completion of the study the code was disclosed and the data were analyzed. Since it is known that prematurity can alter the bilirubin levels simply because of immaturity of the bilirubin conjugating mechanism, the subjects were divided into 230 patients with infants whose birth weights were greater than 2500 grams and 15 with infants of birth weights less than 2500 grams.

In the term infant group the total bilirubin levels were arbitrarily divided into three groups. The length of time between drug administration and delivery was also arbitrarily divided into three periods. There were 119 infants in the drug group and 111 infants in the control group. The data are presented on Table 1. This enumerative data had a Chi square of 15.464 with ten degrees of freedom and a probability of chance occurrence between .10 and .20. Thus there was no significant difference between the bilirubin levels of control and drug-treated infants.

TABLE I

The data from the premature infants are shown on Table 2. There were too few to warrant any conclusions therefrom.

No harmful side effects were noted in any of the patients treated in this study. All of the mothers and their infants survived.

Discussion

Bilirubin is formed by the degradation of hemoglobin through a series of well recognized reactions in the reticuloendothelial system. It is then transported bound to albumin. In this transport one mole of albumin will carry two moles of bilirubin.[4] It is then excreted by a complex process that includes the transfer of the unconjugated bilirubin from albumin across the cell membrane into the hepatic cell, conjugation with glucuronide using the microsomal enzyme glucuronyl transferase, and finally excretion into the bile ducts.

Although bilirubin is formed during fetal life, the enzymatic system for glucuronide conjugation of bilirubin in the liver of the newborn is deficient.[5] Since unconjugated bilirubin is transferred across the placental barrier, the fetus is protected in utero from hyperbilirubinemia.[6,7] The problem then is the removal of bilirubin from the newborn's circulation.

Several substances are known to increase the circulating bilirubin levels in newborns. The first group of drugs act by competition for albumin-binding sites and include sulfas, salicylates, caffeine sodium benzoate, and fatty acids.[8] A second group of compounds compete for the conjugation mechanism. The steroid members of this group include pregnanediol, progesterone, pregnanelone, desoxycorticosteroid and etiocholanolone.[9] Recently Arias and Gartner have shown that occasionally the excess steroid of breast milk, pregnan-3 α 20 β-diol, may act by this mechanism.[10] Some antibiotics, e.g., Novobiocin are also in this group.[11,12] A final group of compounds such as vitamin K act by increasing red blood cell hemolysis.[11,13] Adult jaundice has been shown to follow the phenothiazine drugs, due to a cholestatic

mechanism. In an *in-vitro* study of certain phenothiazine compounds (chlorpromazine, promazine, and pecazine), Hargreaves demonstrated the inhibition of bilirubin conjugation.[14] Whether promethazine acts in any of these ways is unknown.

The permeability of the placental barrier to promethazine has been studied. In one study promethazine was found in the umbilical vein blood as early as 1 1/2 minutes after the intravenous administration of a 50 mgm. dose.[15,16] Equilibrium was achieved with maternal venous blood in 15 minutes, and four hours later the drug was still recoverable from the cord blood.[17] In another study no drug could be demonstrated in the umbilical cord blood.[18]

Several studies have been done to question the possible relationship between promethazine in labor and neonatal jaundice. Scokel and Jones found that promazine and promethazine did not increase the incidence of neonatal jaundice in term infants, but there was some question as to whether there was more jaundice produced in premature infants.[19] Boggs also noted no significant increase in neonatal bilirubin levels at 30-60 hours of age in infants whose mothers received 50 mgm. of promethazine intramuscularly one to six hours before delivery.[20]

The present study was undertaken to extend the experience with promethazine in labor and to study its effect on neonatal bilirubin levels. It was found that the drug did not increase the bilirubin levels of the infants delivered. These results agree with those reported by others.

Summary

A randomly assorted double-blind control study of the use of promethazine in labor was conducted on 245 patients. No increase in the serum bilirubin levels was found in infants whose mothers had received promethazine while in labor.

WHAT'S YOUR DIAGNOSIS?

While shaving this 35-year-old salesman noticed a "funny", burning sensation in his right foot. It bothered enough so that he took off his shoe and stocking to look. There was a slightly reddened area that corresponded to the sensation, but nothing else. A couple of hours later the intensity of the feeling had increased enough so that he again took off his shoe. This time the area was black and gangrenous-looking — about the size of a half dollar on the dorsum of the foot and extending like a saddle between the fourth and fifth toes. The area was sharply circumscribed and the rest of the foot was completely normal. He was hospitalized immediately to seek the cause of this "galloping gangrene".

His past history was negative. He had been in excellent health; there was no family history of vascular disease; the patient had neither taken any drugs nor been exposed to any toxic substances. The physical examination was completely normal. There was no sign of any heart or vascular disease — just the painful black area on the foot that we were happy to see was no longer increasing in size. The routine laboratory tests, blood coagulation studies, serum proteins, electrophoretic patterns, and EKG. were all normal. There were no cryoglobulins. No urine or blood sugar abnormality.

By the second day the situation was unchanged except that the wbc. was up to 9,000 with a very few toxic P.M.N.s. The pathologist felt that the peripheral morphology represented an infectious process. An internist saw him in consultation, and again the history and physical examination revealed no additional findings. It was suggested that this could be an unusual type of strep infection with bacterial thrombi and/or emboli. Anticoagulants and antibiotics were started. We both thought this diagnosis somewhat tenuous and called for a dermatological consult.

This eminent diagnostician walked into the room and had the answer in five minutes by looking carefully and asking questions.

What is your diagnosis? Turn to page 1221.

Riddoch's Syndrome

Visual Disorientation Syndrome

Visual disorientation in homonymous half-fields without loss of stereoscopic vision was described by Riddoch in 1935. Patients with this condition are unable to localize objects seen to one side only. This defect gradually increases from the center towards the periphery of the visual field. The patient is unaware of the defect as there is little or no disturbance of central vision. Loss of visual attention may be present. According to Riddoch this disorder may result from a unilateral lesion of the parietal lobe. Holmes has described defective spatial orientation in the visual fields that may result from a bilateral cerebral lesion.

Orbital Fractures*

JOHN S. HUFF, M.D.
Minneapolis, Minnesota

FACIAL INJURIES are becoming common because of increasing numbers of auto accidents. Orbital fractures may occur in deep areas and may be easily missed, with resultant late disability that cannot be fully restored to normality. Fracture of the floor of the orbit is an example.

The orbital contents are recessed and protected by rather heavy bone, the supraorbital arch of the frontal bone above, the zygoma laterally, the frontal process of the maxilla medially, and the rim of the orbital floor formed by the zygoma and maxilla. Posterior to the rim, the orbital floor (platform) consists of thin, weak bone which separates the orbital cavity from the maxillary sinus.[1] The infra-orbital canal further weakens the floor. The orbital walls are also thin medially at the lamina papyracea of the ethmoid, and laterally at the wall over the temporal fossa.

The stronger areas around the orbital rim may sustain injury without consequence, while force exerted on the orbital contents may cause disruption of the thin areas, particularly the floor. Such fractures may not be obvious. More serious force may cause disruption of the orbital rim with obvious deformity. This is well illustrated by the experiment of Converse et al.[2] on cadavers in which a hurling ball placed over the eye and struck with a hammer caused a cracking sound and resulted in a depressed comminuted fracture of the floor of the orbit along with a displaced fracture of the lamina papyracea. In the second experiment by Converse, the soft tissue overlying the orbital rim was incised to allow direct contact of the bony orbital rim with the surface of the hurling ball. Repeated blows of similar force with the hammer failed to fracture either the floor or the rim of the orbit. However, when the striking force was sufficiently increased, the orbital rim and orbital floor were comminuted simultaneously. It has been observed that a small ball such as a golf ball will rupture the globe, while a large ball, which compresses all of the orbital contents, fractures the floor.

---

*Presented to the Postgraduate Convention in Ophthalmology and Otolaryngology, sponsored by the North Carolina and South Carolina Societies of Ophthalmology and Otolaryngology, September 12-14, 1965.

Since injuries to the orbit are frequently accompanied by other facial, cranial, and bodily injuries, a thorough assessment of the patient is necessary. The extent of injuries should be ascertained so that proper therapy can be instituted immediately. A satisfactory airway must be established.

Diagnosis of Orbital Fractures

1. Inspection. Extraocular muscle imbalance with diplopia in the forward gaze with onset from injury is most suspicious of orbital fractures. Diplopia, when not as obviously explained by inspection, should be evaluated in all directions of gaze, by use of Maddox rod* and prism and cover tests. The traction test is also helpful in differentiating a trapped inferior rectus muscle from a weak superior rectus muscle.
2. Palpation of orbital rim.
3. Sensory testing for anesthesia of the infraorbital nerve.
4. Occlusion of teeth and freedom of the coronoid process.
5. X-ray views with Caldwell, Waters and lateral views, before the patient is immobilized with other appliances.

In diagnosis as well as treatment, close liaison between specialists is necessary.

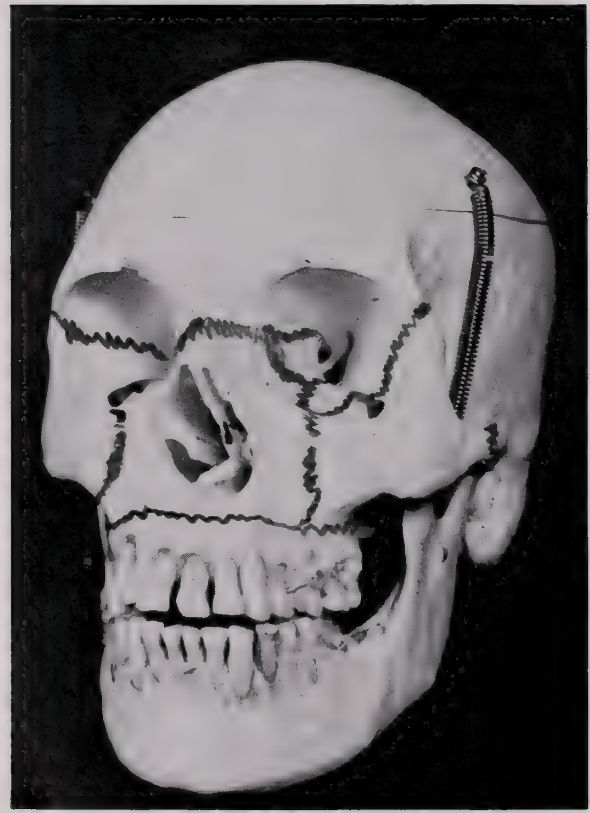

Fig. 1 — Fractures of the orbit may occur alone or in combination with other facial fractures.

Fracture and Repair of the Zygoma

The zygoma forms the buttress of the facial skeleton and has four processes: the frontal and maxillary anteriorly, the orbital and the zygomatic posteriorly. Because the zygoma forms the superior lateral portion of the maxillary sinus, tearing of the mucosa causes bleeding into the sinus which is manifested by x-ray clouding or bleeding from the nose.[1] When the zygoma is displaced and rotated downward with separation at the fronto-zygomatic suture, there is inferior depression of the orbital rim as compared to the normal side. There is also (flattening) of the cheek and downward displacement of the lateral canthus and eyeball from the pull of Lockwood's suspensory ligament and lateral palpebral ligament which are attached to the orbital surface of the frontal process of the zygoma.[4]

Compression or fragmentation of the orbital rim may cause downward displacement of the lower lid from the pull of the septum orbitale. When fragmentation extends to the floor of the orbit or when the floor is fractured while the rim is spared, as in blowout fractures, the orbital contents may become trapped between fragments or may sag into the maxillary sinus, causing diplopia or enophthalmos or both. Impingement of the zygomatic arch[19] against the coronoid process of the mandible causes limitation of motion of the jaw and difficulty in opening and closing the jaw. The proximity of the zygoma to the infra-orbital foramen or canal causes anesthesia of this nerve in some cases. However, this anesthesia is usually temporary unless bone fragments compress the nerve in the canal.

X-ray examination should include Waters,

---

*See Test Your Word Score Page 1267.

Caldwell and vertico-submental views of the zygomatic arch. The Waters is probably the most valuable view, because it shows the orbital rim and floor. Reduction of fractures of the zygoma is usually easy, providing they are diagnosed and reduction is performed within a short time of injury. In some cases of simple fracture a tenaculum may be used in a rotating manner to reduce the fracture. If the position is stable no fixation is necessary.

Gillies Approach

This approach is valuable in reducing fractures of the body as well as fractures of the arch. An incision is made in the temporal area parallel to the temporal vessels and the dissection is continued through the fascia exposing the temporalis muscle. It is necessary to go through the full thickness of the fascia so that the elevator will proceed to the medial surface of the zygomatic arch.

Intra-Oral Approach

Inside the mouth the mucosa lateral to the maxillary tuberosity is incised and, with an elevator close to the bone, the fractured zygoma is elevated upward and outward. This approach cannot be used for fractures of the arch as the masseter muscle interferes with access to the arch.

Maxillary Sinus Approach

This approach is useful in comminuted fractures and fractures of the floor. It is performed through a Caldwell-Luc incision, and frequently a fracture line is encountered. In a suspected fracture of the orbital floor, a disc of anterior maxillary bone can be removed to be utilized later for a defect in the floor. The sinus is suctioned, inspected and palpated with a finger. The fractures, if comminuted, can frequently be easily reduced with the finger. If a Steinman pin is required for immobilization of the zygoma, this is inserted before the antral packing. Packing consists only of a long Penrose drain folded upon itself with a gauze strip left inside for bulk. It may be lubricated with antibiotic ointment. If the sinus is packed, the packing is left in place two to four weeks and then removed. Penrose-drain packing prevents the accumulation of foul-smelling debris and is removed without discomfort to the patient.

Infra-Orbital Approach

Direct wiring is often utilized for zygomatic fractures as it allows a very accurate reduction and fixation. Frequently reduction without fixation is disappointing, as the deformity tends to recur. Direct wiring is used in conjunction with reduction through a Gillies approach. The direct-wiring approaches are over the fronto-zygomatic suture and below the lower eyelid over the infra-orbital foramen. The bone is exposed and drill holes are made with a dental drill and a fine burr,

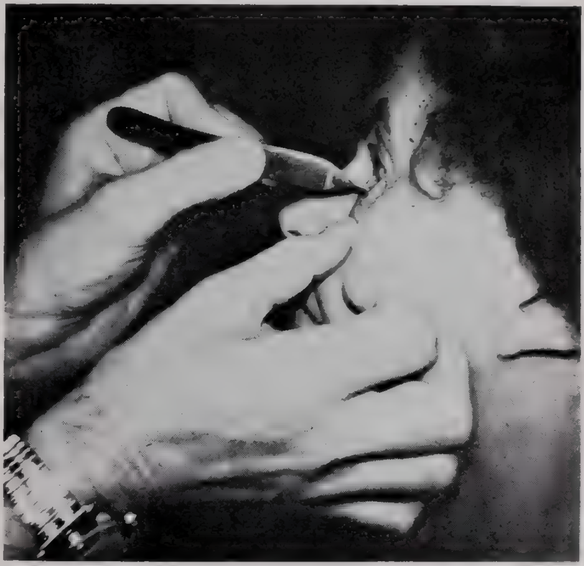

Fig. 2 — Diplopia in forward gaze with onset from injury is most suspicious of orbital fractures.

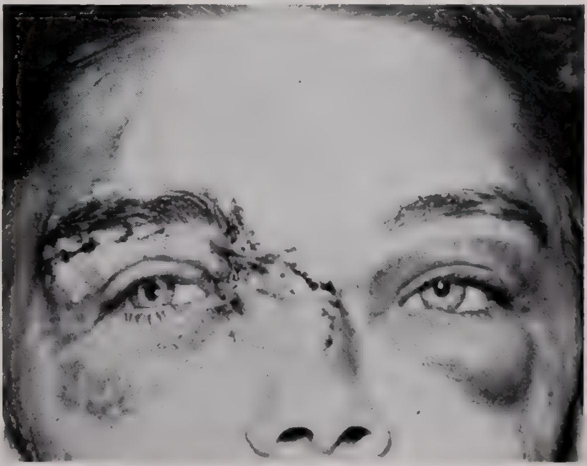

Fig. 3 — The traction test performed under anesthesia differentiates restriction of motion of the inferior rectus muscle from weakness of the superior rectus muscle.

protecting the orbital structures on the exiting side of the bone with a flat instrument. Number twenty-six stainless steel wire is used and can be brought back through a drill hole using a looped number thirty wire.

The infra-orbital approach affords the advantage of direct exposure of the orbital rim and floor by elevating the periosteum, a step that should always be performed whenever an orbital-floor fracture is suspected. Very little reaction is encountered from the interosseous wire or from Steinman pins, although more is seen in the skin from the latter where it is allowed to protrude for removal. The small incisions necessary for direct wiring produce minimal disfigurement.

Fracture of the Maxilla

The maxilla forms portions of the orbit, nasal fossa, oral cavity, and palate. Because of its location and strong buttresses it is injured less often than other facial bones. Fractures of the maxilla were categorized by Le Forte as I, alveolar; II, pyramidal; and III, craniofacial dysjunction. The Le Forte I can be quickly ascertained by grasping the upper teeth, checking occlusion, and obtaining an x-ray examination, especially a lateral view to show fracture lines of the anterior and posterior wall of the maxillary sinus. The Le Forte II may produce an irregular infra-orbital margin and the Le Forte III, characteristic elongation of the central portion of the face. Unilateral fractures can occur in such areas as a portion of the alveolar ridge or infra-orbital area. Fractures of the maxilla cause bleeding and swelling in the airway, and intermaxillary fixation is usually necessary. A tracheotomy may also be required in this type of fracture.

Treatment of these fractures may be performed by closed reduction and intermaxillary fixation, by open reduction and wiring in the pyriform aperture or infra-orbital area, or by fixation with an appliance attached to a head cap. The latter has disadvantages in the craniotomy patient because of discomfort and the scarring from traction wires placed through the skin. Transantral reduction and packing is utilized freely in treatment.

Floor of Orbit Fractures

Diplopia with loss of normal extraocular muscle function is a common symptom of blowout fractures. Ecchymosis and edema may be present to mask an enophthalmos that would occur after swelling subsides. There may be complete fixation of the globe or limitation of upward, downward, or lateral gaze. Traction on the inferior rectus does not cause the globe to elevate. This differentiates restriction of motion of the inferior rectus from weakness of the superior rectus.[2,3,4] Anesthesia in the area of the infra-orbital nerve is a helpful diagnostic sign when the orbital rim is not fractured. X-rays show a cloudy maxillary sinus, and planigrams may show the sac of orbital contents hanging down.[2,3,4] However, in spite of normal x-rays clinical suspicion of orbital floor fracture warrants exploration.

The infra-orbital approach is best for examination purposes. By elevating the periosteum of the floor, a fracture can be seen. If a fracture is present and cannot be reduced from above, the maxillary sinus can be opened and, by using a combined approach, the contents of the orbit can be reduced. Some fractures are hinged on either side and, as the contents are pulled up, they are caught in the trap-door deformity. Others show a defect that needs bridging with a piece of bone, such as from the anterior face of maxilla or ilium, or simply antral packing. Occasionally the trauma to the inferior rectus muscle results in the eye deviating upward for a period of time until the muscle function is normal. Late repair of orbital floor fractures is not as satisfactory as early repair, as fibrosis and shortening of the muscles occur, and loss of orbital fat may cause persistent enophthalmos even with repair of the floor.

Frontoethmoid Fractures

These involve the medial and superior aspect of the orbit. The interorbital space is composed mainly of the ethmoid labyrinths. The thin medial wall is the lamina papyracea. The heavy frontal bone protects the eye, the frontal sinus and the frontal lobe, but severe injuries fragment the posterior wall of the frontal sinus, the cribriform plate and ethmoid labyrinth, and the floor of the anterior cranial fossa. These may produce a cerebrospinal fluid rhinorrhea and widening of the intercanthal distance. The medial canthal ligament may also become detached, and injury may occur to the lacrimal system.

Reduction of a depressed frontal fracture may be accomplished through the wound or through a horizontal eyebrow incision. If the eye is pushed downward or ptosis is present from a supra-orbital rim fracture, open reduction and direct wiring may be needed. Severe injuries to the nose may extend into the ethmoid labyrinth, causing widening of the interocular space and involvement of the cribriform plate. This should be reduced by elevation and fixation of nasal bones with wire. Open reduction of the medial orbital wall may be necessary. McCoy describes the use of an Ash forceps through bilateral inner canthal incisions to narrow a widened ethmoidal complex.[5] When the medial canthal ligament has become detached, it should be restored to its normal position by direct wiring to bone. The lacrimal apparatus when injured should be repaired after complete healing of the fractures has taken place.

Summary

A high index of suspicion is necessary to diagnose orbital fractures, as many of the obvious manifestations do not occur until all swelling has subsided. Early treatment is necessary to prevent limitation of function, especially in orbital-floor fractures.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 1216)

"That's a burn, not gangrene," the eminent diagnostician declared. Then he asked, "Have you been around heat, cold, electricity, acid, alkali, lye, lysol, caustics, solvents, cleaning agents?

He got a negative answer to each of those questions, but as he paused to think up other categories, the patient said, "Say, wait a minute; an hour or so before I shaved that morning I used some Draino to unplug a laundry tub drain for my wife, and I spilled a little on my shoe. I didn't think anything of it because it didn't get near my skin."

Close examination of the shoe showed a break in the stitching exactly over the black area on the foot where the Draino must have dripped, causing the burn. Needless to say, all treatment was stopped; he was discharged that day, and once again the importance of an accurate, persistent history was demonstrated.

The school of experience never changes; it always has and always will issue its diplomas on the roughest grade of sandpaper! — Magazine Digest

To be young in mind and heart in a senile and disillusioned world — this it is to be educated. — Nevile Watts

Electric Rings

Another favorite electrical contrivance of the last quarter of the nineteenth century, though I have seen them worn by old men in the twentieth, were the so-called electric rings . . . They were supposed to be worn on the third finger of the left hand because according to a very old tradition there is a vein or artery — or something — which goes directly from this finger straight to the heart. That is, after all, as is very well known, the reason why the marriage ring is worn on that finger.

I have seen thoroughly intelligent men wearing these rings, and I knew a man who made — and kept — a quarter of a million dollars, not only to wear one of these rings himself for years, but to delight in sending examples of the ring to his friends, perfectly sure that they would relieve their pains and aches; for the ring was almost a panacea** for all rheumatic conditions, such as muscle and joint troubles that might be worse in rainy weather.

This good man used to take off his ring in my presence and a little ostentatiously wipe out the inside of it and then show me the brown stain which was to be found on his handkerchief. He was wont to explain that this was the disease material which the ring "drew" out of him every day and that had it been allowed to remain in his system he would undoubtedly after a time have come down with an attack of either gout or rheumatism; or perhaps the retention of this effete material would have predisposed him to other and more serious affections.

It was a very naive explanation of the mystery of disease, but it was fully accepted and many thousands of people bought the rings and most of them were, for a time at least, benefited, if not actually cured by this electrical energy which was flowing from their third finger into their very heart's core all the day and all the night long and doing them good. The rings sold themselves or at least enthusiastic wearers who had been "cured" or greatly relieved gave their testimonials and recommended them to all who would listen.*

Society for Cryo-Ophthalmology

The Society for Cryo-ophthalmology has been formed to promote investigative and clinical applications of low-temperature technics to the eye. Applications for membership will be welcomed from those interested in the investigative aspects of this subject, the preservation of ocular tissue, therapeutic applications of cryogenics to various ocular diseases, and cryosurgical technics. It is contemplated that scientific meetings will be held immediately prior to the annual sessions of the American Academy of Ophthalmology and Otolaryngology.

Inquiries and applications should be addressed to Dr. John G. Bellows, 30 N. Michigan Blvd., Chicago, 60602.

Praise from a Saint

The physician that bringeth love and charity to the sick, if he be good and kind and learned and skilful, none can be better than he. Love teacheth him everything, and will be the measure and rule of all the measure and rules of medicine. — Savonarola (1452–1498)

The Syndrome of Ankyloglossia Superior

PHILIP M. MARDEN, M.D.*
Minneapolis, Minnesota

THE SYNDROME of ankyloglossia superior (attachment of the tongue to the roof of the mouth) is a very rare congenital anomaly, and few cases have been reported in the literature.[1-9] The author has recently had the opportunity to examine a patient with this syndrome who, in addition to the usually associated anomalies, also had malformations of the brain and heart.

Case Report

This patient was the product of a full-term pregnancy which was complicated by spotting in the first trimester and attacks of nausea, vomiting, and abdominal pain throughout the gestational period. An upper gastric series, barium enema, and gallbladder roentgenograms were performed on the mother approximately one month before conception. Propantheline bromide with thiopropazate dihydrochloride, chlordiazepoxide hydrochloride, but no meclizine hydrochloride containing drugs were prescribed during the first trimester. The 32-year-old mother, the 36-year-old father, and a 28-month-old male sibling have been in relatively good health. There is no family history of congenital malformations or consanguinity.

On February 9, 1965, the infant was delivered in a cephalic presentation and resuscitation was required because of the accumulation of mucus. Birth weight was 3,402 grams, length 56 cm., and head circumference 33.5 cm. Multiple congenital anomalies including the attachment of the tongue to the palate were noted. He was fed by means of a polyethylene catheter. On the sixth day of life he was transferred to St. Paul Children's Hospital for surgery.

On admission he appeared to be a lethargic and mildly cyanotic baby. Immobility of the facial muscles, bilateral esotropia and micrognathia were present (Figure 1). The tip of the slightly small tongue was adherent to the hard palate in such a manner that the posterior pharynx could not be visualized (Figure 2). No cardiac murmurs were heard and the femoral pulses were palpable. The lungs were clear to percussion and auscultation. The liver was felt just below the costal margin. Only two completely developed fingers were seen on the left hand and none on the right. Bilateral severe talipes equinovarus was noted. The patient had a weak cry, poor Moro response, and decreased deep tendon reflexes.

Laboratory studies including a hemoglobin, white blood count, differential, urinalysis, and electrocardiogram were normal. Chromosomal analysis on peripheral leukocytes revealed a normal complement. Except for the two formed digits on the left hand, roentgenographic studies showed absence of the carpals and phalanges and abnormal metacarpals

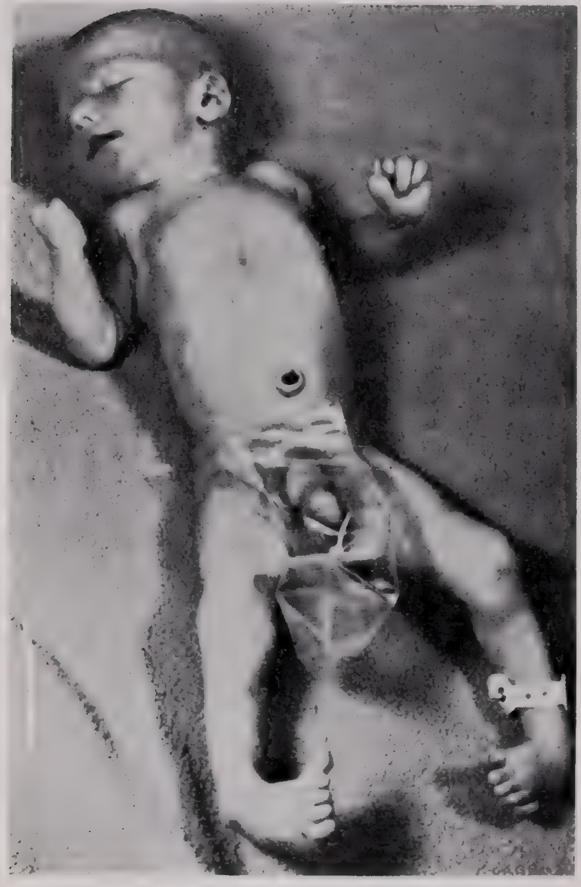

Fig. 1 — Full-length view of the infant.

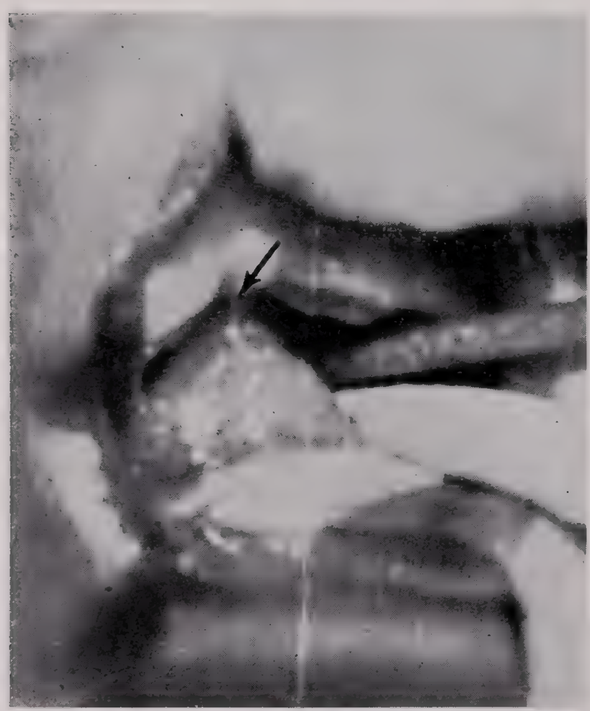

Fig. 2 — Close-up of mouth showing adhesion of the tongue to the palate. (arrow)

(Figure 3). The cardiac silhouette appeared normal and a healing fracture of the middle third of the right clavicle with moderate callus formation was demonstrated.

On February 17, 1965, the broad attachment of the tongue to the palate was divided and the bleeding controlled by pressure and interrupted catgut sutures. A cleft of the soft palate and posterior portion of the hard palate then became visible. Recovery after surgery was uneventful.

He was transferred to Gillette State Hospital on February 26, 1965, for the correction of the equinovarus deformity. A series of plaster casts were applied to the feet and changed approximately every ten days. He developed frequent generalized grand-mal seizures which were controlled with calcium gluconate, phenobarbital, and diphenylhydantoin. At three months of age the child could neither smile nor hold his head up. He died suddenly on the night of May 30, 1965.

Autopsy Findings

The body was that of a three-month-old male infant with multiple congenital anomalies. The child weighed 3,800 grams and measured 59 cm. The heart weighed 30 grams and had a normal external configuration. A valvular competent foramen ovale and a bicuspid aortic valve were demonstrated. A one-cm. mildly hypoplastic segment of the aorta proximal to the closed ductus arteriosus and distal to the left subclavian artery was noted. Curdled milk was distributed from the major bronchi down into the distal bronchioles. The abdominal organs were grossly normal. The brain weighed 430 grams and had a normal external configuration. Sagittal section revealed dilation of the ventricular system with obstruction of the upper portion of the aqueduct. An intact cavum septum pellucidum* with some atrophy of the corpus callosum was found. The cranial nerves and the circle of Willis appeared normal.

Microscopic examination of the lungs revealed plugs of amorphous foreign material within the bronchi, bronchioles, and alveoli. There were several areas of peribronchiolar inflammatory cellular infiltration. The liver showed acute diffuse congestion. Focal areas of gliosis were present in the pons and tegmentum of the midbrain. Histological examination of the remaining organs was normal.

Comment

Individuals with the syndrome of ankyloglossia superior have malformations of the tongue, palate, cranial nerves and distal ends of the extremities. Two patients have had involvement only of the tongue and palate.[1-4] The short rudimentary tongue may be inserted into the hard palate, alveolar ridge,[1,4] or lower portion of the nasal septum.[2] Hypoplasia of the palatine structures of cleft palate is a frequent associated finding. Paralysis of the facial nerve and, in one instance, the abducens nerve[6] is a common yet unexplained defect. Partial or complete adactylia, syndactylia, and hemimelia* have been observed. Anencephaly,[5] epicanthal folds,[6] low set auricles,[6] ankylosis of the mandibular joint[6,7], and skin atrophy of the hands[7] have been reported in isolated cases. Hydrocephaly and cardiac malformations were present only in this patient.

---

*See Test Your Word Score Page 1267.

Oral anomalies including glossopalatine fusion, cleft palate, and micrognathia have been induced in the offspring of rats treated with meclizine hydrochloride or large quantities of Vitamin A.[10] No relationship has yet been established between the use of drugs during pregnancy and the occurrence of ankyloglossia in man. Ingestion of propantheline bromide, thiopropazate dihydrochloride, and chlordiazepoxide hydrochloride during pregnancy has not been known to cause anomalies in the fetus.

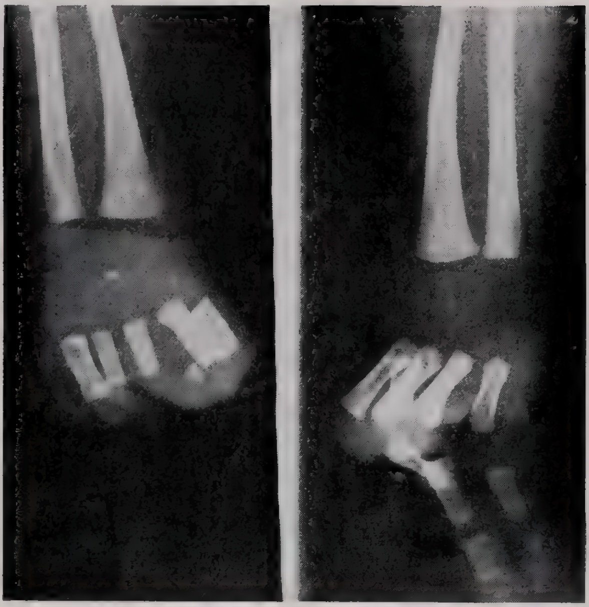

Fig. 3 — X-rays of hands illustrating absence of the phalanges except for two digits on the left.

Summary

Heretofore undescribed associated anomalies of the brain and heart were demonstrated at autopsy in a three-month-old male with the syndrome of ankyloglossia superior.

The author expresses appreciation to Drs. Frank Hedenstrom and Andrew C. Erlanson, the pediatricians, and to the pediatric surgeon, Dr. N. Logan Leven, for consenting to this study of their patient. The autopsy was performed by Dr. Robert D. Fedor at the Charles T. Miller Hospital, St. Paul, Minnesota.

IT'S THE LAW

Recent Court Decisions Tend to Favor Patients*

The trend of court decisions rather than any great increase in the number of suits is the concern of doctors and insurers. An AMA survey indicates an increase of but .2% in the number of malpractice suits; yet over the same period of time the cost of insurance for malpractice has tripled. One specialist in urology expects to pay $861 a year for protection against claims up to $100,000 and a total of $300,000. Doctors and defense lawyers say the rise in insurance rates represents a greater number of judgments and higher awards against the doctors. One of the largest judgments of $725,000 was awarded a 43-year-old Philadelphia lawyer who charged that doctors injured him by leaving some radioactive dye in his sinuses during World War II. The patient sustained great damage to his face and the loss of one eye.

Although medical ethics requires a doctor to render service to strangers injured in an accident, a survey indicated that 46% of doctors feared malpractice suits for doing so. Last year a Brooklyn postman, shot accidentally, stumbled into the office of a specialist in internal medicine who was reluctant to treat him. He sought treatment elsewhere and recovered. The specialist was suspended for a month from membership by the Kings County Medical Society.

Another method of bringing suit is the "informed consent." The doctrine of consent has recently been expanded considerably. It is now accepted legal opinion that a patient cannot give consent unless he is warned of the risk that may attend a particular treatment. An example is the case of a mental patient in Missouri whose wife signed a permit for shock treatment advised by his psychiatrist. During the treatment the patient had convulsions and was seriously injured. Although there was no testimony indicating neglect, the jury awarded a $15,000 verdict. Later the supreme court reversed the verdict on other grounds but specifically noted that the patient had not given informed consent.

Thirty-four states have passed "Good Samaritan" laws giving freedom from suit to a doctor who renders aid under emergency circumstances. However, the American Medical Association states that it has no record of any case in which a doctor has been required to pay damages for being a good Samaritan.

I have served on the record committees of service hospitals and found charts with inadequate records; incomplete charts of several weeks' standing cannot be accurately completed. Some charts had no record of the removal of drains or stitches placed at the time of surgery, and many other defects were found in the records which might have been very harmful to both the doctor and the hospital if used as evidence in a court.

Lung Scintiphotography*

ROBERT D. BUGBY, M.D.**
MERLE K. LOKEN, Ph.D., M.D.†
Minneapolis, Minnesota

THE DIAGNOSIS OF pulmonary disease by methods of radioisotope scintiphotography‡ of the lung is a relatively new procedure in nuclear medicine. This technique has become quite popular, following the pioneer work of Taplin and associates[1] as well as Wagner and associates,[2] who used rectilinear scanning devices to outline the pulmonary vascular bed following the administration of macroaggregates of serum albumin tagged with 131 iodine.

During the past 14 months we have performed 115 scintiphotographic studies of the lung at the University of Minnesota.[3] It is the purpose of this presentation to demonstrate our technique, to give examples of our results, and to relate the various devices and radioisotopes we employ for obtaining these lung scintiphotograms.

The majority of our studies to date have been performed by using macroaggregates of iodinated albumin and a rectilinear scanner. These macroaggregates have an average size of 50 microns and are deposited in the vascular bed of the lung following intravenous administration. They remain fixed for a sufficient length of time to permit a scan to be obtained of the entire thorax, which usually takes about one hour. More recently we have been using 99m technetium labelled to macroaggregates of serum albumin together with our scintillation (Anger) camera to study pulmonary pathology.[4] This latter approach is advantageous because larger doses of the short half-life 99m technetium can be used with the scintillation camera.

Method of Administration

The macroaggregates of albumin are administered with the patient in a supine posi-

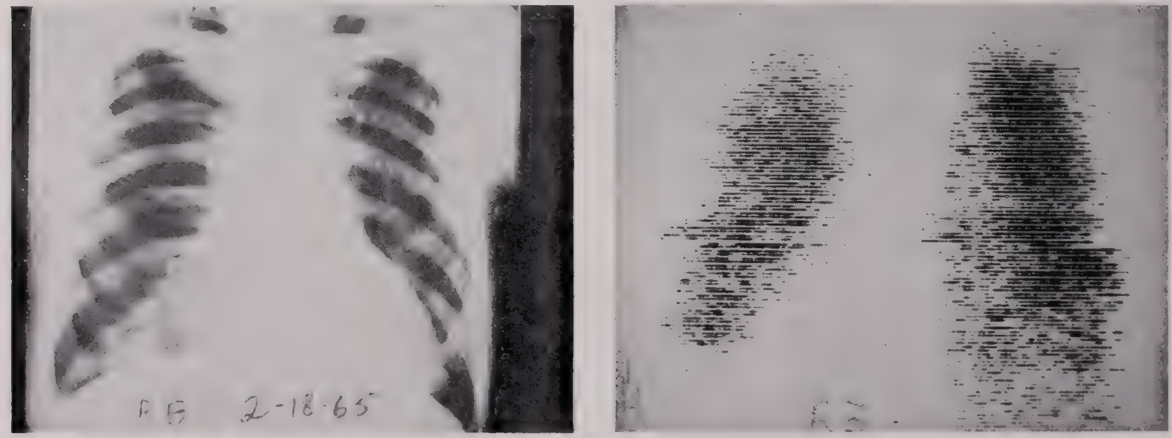
tion. He is instructed to breathe deeply in order for the material to be equally distributed throughout the vascular spaces of the lung. Patients receiving 300 microcuries of the iodinated preparation are then placed under the rectilinear scanner; then, using 0.3 centimeter line spacing and a scanning speed of 60 centimeters per minute, the lungs are scanned from the bases toward the apices. When possible the scan is obtained with the patient prone in order for the bases to be more adequately visualized. We prefer to have chest roentgenograms obtained as close to the time of scanning as possible. These x-rays are taken with the patient in the same position as that used for the scan in order to better equate the position of the diaphragm and expansion of the thorax. A major disadvantage of this method is the length of time required for a single scan. Times in excess of one hour are often required; this presents difficulties for most patients, particularly those who are seriously ill.

Because of these disadvantages we were led to the use of macroaggregates of albumin tagged with 99m technetium together with the scintillation camera. In this method we administer five millicuries of the isotope intravenously with the patient in the supine position, as done with the radioactive iodine preparation. Immediately after the injection the patient is placed in a sitting position and the scintiphotogram is obtained with the scintillation crystal of the camera placed against the posterior aspect of the thorax. With this technique scintiphotograms are obtained in a few minutes. Several projections are usually obtained in studying large patients in order to cover the entire lung fields. The posterior upright position is obtained in these studies to more adequately compare the scintiphotograms with the conventional PA chest x-rays. Other projections (anterior and oblique) are obtained as thought necessary.

Results

We have studied 115 patients using either of the techniques mentioned in earlier paragraphs and find that suitable results may be obtained with either the macroaggregates labelled with 131 iodine or with 99m technetium. The latter preparation is preferred because larger quantities of the radioactivity may be administered to the patient without undue radiation exposure. We estimate that the total body radiation exposure to a patient receiving 300 microcuries of 131 iodine macroaggregates of albumin is approximately 100 millirads, whereas a patient given 5 millicuries of 99m technetium macroaggregated albumin receives less than 10 millirads of total body radiation. Interpretations of scintiphotograms from the scanner and scintillation camera appear to be equally good in the diagnosis of pulmonary abnormalities.

Of the 115 patients on whom we have ob-



PA CHEST SCINTISCAN

Fig. 1 — Roentgenogram and photoscan of lungs on a 52-year-old male. Scan was obtained by using macroaggregated albumin tagged by 131 iodine. Note infiltration in right medial base corresponding to the area of absent activity on the photoscan. Irregularities in the area of the midlung fields are due to patient movement.

tained scintiphotograms of the lung, we have studied 78 in sufficient detail to be included here. These patients may be divided into groups based on a positive or negative scintiphotogram and a positive or negative chest roentgenogram.

Abnormal Scintiphotogram with Pulmonary Pathology

Forty of our patients studied were found to have both abnormal scintiphotograms and evidence of pulmonary pathology on their chest x-rays; 19 were found to have emboli as the primary pulmonary problem. Other causes for abnormal scintiphotograms and chest x-rays were variable, with pneumonia and tumor being the most common.

Abnormal Scintiphotogram without Pulmonary Pathology

A second group of patients were found to have abnormal scintiphotograms and normal chest x-rays; a combination of findings was seen in 15 of the patients, eleven of whom had a good clinical story for pulmonary embolism. Further evaluation based on pulmonary angiography, lung biopsy or autopsy confirmed the clinical diagnosis in all of these patients. The final diagnosis was pulmonary embolism in 12 of these patients.

The remainder of the patients had negative scintiphotograms. A few of these were found to have abnormal chest x-rays with the remainder having normal chest x-rays. There were no patients in this group with negative scintiphotograms who were proved later to have pulmonary emboli. Such diseases as pneumonia without consolidation and pulmonary metastases showed abnormal chest x-rays, whereas the vast majority of the patients with normal chest x-rays were

found to have some cardiac abnormality.

Case Studies

The following are four examples from our studies showing results obtained from both the rectilinear scanner and scintillation camera.

Case No. 1

Figure 1 shows the roentgenogram and scintiphotogram of a 52-year-old white male who was admitted with the acute onset of chest pain which was thought to be related to a coronary thrombosis or to multiple pulmonary emboli. On admission on February 3, 1965, the chest film revealed a small right pleural effusion. On February 17, 1965, the patient complained of severe chest pain on the right side and hemoptysis. The chest x-ray at that time revealed some increased density of a diffuse nature in the right lower lung field, and a lung scan showed a marked decrease in perfusion of the right lower lung field and also the right central lung field. The patient continued on a steady downhill course and expired on February 20, 1965.

Autopsy revealed two infarcts in the right base, one of recent onset and one considered to be of several weeks' duration. A large embolus was found in the pulmonary vessels perfusing this lung field.

Case No. 2

Figure 2 shows the results of roentgenographic and scanning procedures performed on a 37-year-old white male who was admitted to the hospital because of progressive dyspnea and fatigue over the past eight months. The clinical impression at the time of admission was multiple pulmonary emboli. A chest film on September 14, 1965, was thought to show relative radiolucency of the left lung and right lower lung when compared to the remainder of the pulmonary parenchyma. A lung scan on the same day showed decreased perfusion in the right upper lung field and left middle and lower lung fields and was interpreted as being most compatible with multiple pulmonary emboli. A pulmonary angiogram was then performed and reported as normal, as was also a repeat chest roentgenogram taken on September 21, 1965. A repeat lung scan on September 20, 1965, showed a continuance of abnormalcy with marked decrease of perfusion of the right upper lobe and almost all of the left lung, with some improvement in the perfusion of the left base. A lung biopsy showed microscopic findings compatible with previous pulmonary emboli.

Case No. 3

Figure 3 shows the pulmonary studies performed on a 47-year-old white male who was admitted to the hospital with hemoptysis and some dyspnea. Chest film at the time of admission showed a relatively well localized, round density in the left inferior hilus; subsequent work-up revealed carcinoma of the lung. A lung scan showed a marked decrease of perfusion in the left midlung field, an example of how the pulmonary vasculature can be compromised by intrapulmonary masses. The pulmonary angiogram likewise showed marked decrease in perfusion of the midportion of the left lung.

Case No. 4

Figure 4 shows the roentgenograms and scintiphotograms obtained on a 67-year-old white male whose only complaint was the sudden onset of severe dyspnea. He had had similar episodes of dyspnea one year before when he had had thrombophlebitis. Plain chest films were interpreted as normal. The patient received 5 millicuries of 99m technetium tagged with macroaggregates of albumin, followed by scintiphotograms obtained with our scintillation camera. Three areas of decreased activity were seen, two involving the midportions of both lungs and one involving the right apex. A pulmonary arteriogram was obtained which showed delayed perfusion to the same areas previously demonstrated on the scintiphotograms, as well as the deposition of a saddle embolus involving both pulmonary arteries. This embolus was found at surgery to have markedly attenuated the lumen of the arteries to the right apex, right midlung field as well as the left midlung field.

PA CHEST SCINTISCAN PULMONARY ARTERIOGRAM

Fig. 3 — Pulmonary studies on a 47-year-old male with carcinoma of the left lung. Note the localized density in the left inferior hilus on the roentgenogram. Photoscan shows decreased activity in the left midlung field proved to be due to vascular occlusion of the pulmonary vessels to this area by the carcinoma as shown on pulmonary arteriogram.

Discussion

Since the macroaggregates are caught in the vascular system of the lung there is an area of absent or decreased activity on the scintiphotograms because the injected material is not able to get to the peripheral pulmonary vascular bed. Therefore, lung scintiphotograms show areas of absent or decreased perfusion related to abnormalities in lobar or segmental distribution of pulmonary blood flow. It is therefore apparent that any process which compromises or occludes the pulmonary vasculature will produce an abnormal lung scintiphotogram, a finding which appears to be most useful in the diagnosis of pulmonary embolization. The particular finding considered most significant in pulmonary embolization is a crescent-shaped area of decreased perfusion in the peripheral lung field.[2] It is well known that pulmonary embolization can occur without infarction of the lung tissue; consequently lung scintiphotography is of particular value when embolization is suspected but no evidence of an abnormality on plain chest roentgenograms is seen.

Other pulmonary abnormalities may also cause decreased or absent activity. Among

these are tumors, pneumonia in a state of consolidation, atelectasis, pulmonary sequestration, pulmonary abscesses, and large pleural scars.[5] In these latter cases the chest x-rays are invariably indicative of pulmonary pathology.

Conclusions

It is our impression that scintiphotography of the lung is a valuable diagnostic tool, especially in the diagnosis of pulmonary embolization in which there has not been evidence of infarction on plain chest films. Although we cannot make a definite diagnosis of pneumonia or tumor by the use of scintiphotography of the lung we still feel that serial scans in these diseases can very readily follow the course of the disease. It is also our opinion that the use of short half-life isotopes in relatively high dosages with the use of the scintillation camera is perhaps preferrable to conventional rectilinear scanning because it takes less time to perform, therefore causing the patient less discomfort. We are able to obtain this information much more rapidly by administering relatively larger amounts of radioisotope than if we were to use low doses of longer half-life isotopes using the scintillation camera. One disadvantage of the camera, however, is its limited field necessitating several views in the examination of a larger individual.

The Use and Abuse of Thyroid Hormone

RONALD OLIN, M.D.*
Fargo, North Dakota

PHYSICIANS CAN BE classed as conservative or liberal in advising thyroid hormone for their patients. The purpose of this paper is to present a conservative approach to the use of thyroid hormone. The areas of abuse and the specific indications for thyroid hormone will be discussed.

General Considerations

There are several gradations between euthyroidism** and hypothyroidism. It is important to detect abnormalities in thyroid function by a careful history, physical examination and appropriate laboratory tests, but not by any one of these alone.

A hypothalamic humoral factor, so-called thyrotropin-releasing factor, stimulates the synthesis and discharge of anterior pituitary thyrotropin. Thyroid-stimulating hormone stimulates the thyroid gland to secrete thyroid hormone. Thyroxine and triiodothyronine inhibit thyroid-stimulating hormone and probably thyrotropin-releasing factor by a feedback mechanism.[1] In euthyroid patients the administration of desiccated thyroid inhibits endogenous production of thyroxin by suppressing thyroid-stimulating hormone. Thus, exogenous thyroid up to a certain point merely acts as replacement for endogenous thyroxin, causing no definite change in the clinical status or thyroid function tests. Greer[2] found that within one week of thyroid administration the thyroid gland activity, as measured by the I-131 uptake, could be greatly reduced. In over 90 per cent of patients the daily dose required was 60 to 180 mg. As much as 600 mg. per day was required in some subjects to accomplish this effect.

In thyroid-treated euthyroid patients, approximately two weeks are required for the thyroid uptake of I^{131} to become normal after cessation of therapy. Some patients require several months for complete recovery.

---

*Department of Internal Medicine, Fargo Clinic.
**See Test Your Word Score Page 1267.

Until the thyroid gland takes over active production of hormone again, the patient may not feel well; he may experience fatigue, malaise, muscular aching and emotional lability (Fahrquason phenomenon). A few patients following cessation of thyroid therapy have a "super-rebound" of sufficient magnitude to cause permanent thyrotoxicosis. Patients treated with thyroid continuously for many years experience just as much return of thyroid activity as those treated for a few weeks. Thus, there is no reason to give thyroid hormone to euthyroid patients.

Thyroid Function Tests

The serum cholesterol determination, due to its wide variations in normal, is the least useful test of thyroid activity. The basal metabolic rate is an unreliable test in mild hypofunction of the thyroid. The I^{131} uptake is better in the diagnosis of hyperthyroidism but is of much less value in establishing the diagnosis of hypothyroidism. The thyrobinding protein index and the erythrocytic triiodothyronine uptake are more subject to laboratory error and interference by drugs.

The serum protein-bound iodine (or butanol-extractable iodine) is the most reliable test for hypothyroidism. The usual range of normal is 4 to 8 micrograms per cent.

The Achilles reflex, observed visually or by means of an electromagnetic recording device, is a simple and helpful adjunct in the diagnosis of thyroid disorders.[3]

Hypometabolism Without Myxedema ("Metabolic Insufficiency")

The syndrome of hypometabolism without hypothyroidism occurs more commonly in women than men and between the ages of 15 and 40 years. The subjective complaints are fatigue, weakness, cold intolerance and constipation. Physical examination reveals obesity and brittleness of hair and nails without the classical skin and deep tendon reflex changes of hypothyroidism. The basal metabolic rate is usually between minus 15 and minus 30. Some of these patients receive initial benefit from thyroid hormone, and with increased doses more subjective benefits result. Other patients derive no benefit from treatment.

Levin[4] studied such a group of patients with the basal metabolic rate in the minus range and a normal protein bound iodine and I^{131} uptake. Over 75 per cent of patients complained of constipation, fatigue and tension, and 40 per cent had cold intolerance. Treatment with thyroxin, triiodothyronine and a placebo in a controlled double-blind study demonstrated that the thyroid hormones had no beneficial effect.

More intensive studies are necessary to establish the exact nature of this disorder. The defect may well be in general body metabolism. Some physicians advise a trial of thyroid hormone in this group. Unfortunately, patients may be lost to follow-up and just keep renewing their prescriptions for thyroid hormone. The author does not give thyroid to these patients.

Thyroid Hormone in Obstetric and Gynecologic Diseases

Thyroid hypofunction in both the pregnant and nonpregnant phases requires careful clinical appraisal of the patient, combined with thyroid function tests, and occasionally a therapeutic trial.

During pregnancy the basal metabolic rate shows a progressive rise beginning in the fourth month and rises to about plus 16 at term. The determination of the protein bound iodine in pregnant women also shows a trend towards higher values, reaching levels of 11.2 micrograms per cent. The rise takes place over no particular period of the pregnancy; it occurs in the sixth or up to the twelfth week. The elevation in protein bound iodine does not correlate with the rise in basal metabolic rate. Pregnant women also have slower reflexes than nonpregnant.

Pregnancy is rare in the hypothyroid female, and the incidence of spontaneous abortion is increased should pregnancy occur; but pregnancy itself does not alter hypothyroidism. Russell[5] felt that correcting low protein bound iodine levels improved the prognosis for the successful continuation of pregnancy, thus minimizing threatened and habitual abortion. Singh and Morton[6] showed that low protein bound iodine levels were not associated with abortion and that increased levels did not guarantee against abortion; they also questioned the wisdom of giving thyroid hormone routinely in threatened or habitual abortions. Naumoff and Shook[7] felt that pregnancy caused thyroid decompensation with less available thyroid hormone in women with "low thyroid reserve" leading to spontaneous abortion.

Correcting hypothyroidism is also important in the nonpregnant period to prevent infertility, anovulation, and menorrhagia.[8]

The emperic use of thyroid hormone without clinical or laboratory indications other than infertility, menorrhagia, or first trimester abortion has lead to its discredit.

Thyroid Hormone in Other Diseases

Deafness and occasionally tinnitus and vertigo can be present in myxedema. Some otologists use thyroid hormone empirically, with nicotinic acid, procaine, or lipoflavenoids in treating hearing problems of uncertain cause.[9] Neurologists observe that patients with narcolepsy or those who are "sleepy normal" are referred to them for evaluation, and they are commonly on thyroid hormone.[10]

Without clinical and laboratory evidence of hypothyroidism, these are misuses of thyroid hormone.

Specific Indications for Thyroid Hormone

Thyroid hormone is indicated in the following disorders:

1. Primary or spontaneous myxedema of adults (Gull's disease) or of children (juvenile myxedema).
2. Cretinism.
3. Post-surgical or radioiodine hypothyroidism (cachexia strumipriva).
4. Pituitary myxedema (part of panhypopituitarism, isolated thyrotropin deficiency, pituitary dwarfism, or acromegaly.)
5. Hypothyroid phase of acute granulomatous thyroiditis.
6. Hashimoto's thyroiditis (with or without hypothyroidism).
7. Simple goiter.
8. Hyperophthalmia of Grave's disease (pituitarigenic oculopathy).
9. Cancer of the thyroid gland.

General Considerations in the Use of Thyroid Hormone

The adequacy of the dose of thyroid hormone in treating myxedema is best evaluated by the clinical response. There is a considerable difference in the requirements of patients for thyroid hormone as indicated by the observation that some can take 180 mg. daily without signs of overdosage, whereas others can take 600 mg. with impunity. The usual therapeutic dosage in otherwise healthy patients is 60 to 180 mg. (1 to 3 grains) daily. A single daily dose is adequate particularly with desiccated thyroid and 1-thyroxin. There are several thyroid preparations available and the physician is advised to become familiar with and use only one or two of them:

Types of Thyroid	Dose Equivalents
Desiccated thyroid	60 mg. (gr. 1)
Sodium 1-thyroxin (Synthroid (R))	0.1 mg.
2-L-triiodothyronine (Cytomel (R))	25 mcg.

If doubt exists regarding the original diagnosis of hypothyroidism, the patient should be advised to stop thyroid hormone for two months and return for a clinical re-evaluation and appropriate thyroid function tests. Some endocrinologists advise a thyroid-stimulating hormone test to assess the potential thyroid function of the patient while he is being treated with thyroid hormone. Thyroid-stimulating hormone will stimulate the uptake of I^{131} by the thyroid gland, which is suppressed by exogenous thyroid hormone but is potentially capable of function.

The requirement for thyroid hormone falls with advancing years and the dose may therefore have to be decreased. Thyroid hormone should be used with caution in patients with angina pectoris, recent myocardial infarction, congestive heart failure, adrenal insufficiency, anoxic states, diabetes mellitus and psychiatric disorders.

Some of the more common specific indications for thyroid hormone will be discussed briefly.

Primary Myxedema of Adults

The disease is insidious in onset with cold intolerance, coarse and dry skin and hair, decreased sweating, pallor, slow and husky voice, edema of eyelids and hands, weight gain, deafness, menorrhagia, hypertension, bradycardia, low pulse pressure, slowing of the deep tendon reflex return (Woltman's sign), slow cerebration with poor memory, irritability, and possible psychosis and decreased drug tolerance.

If the clinical features are equivocal and the laboratory studies borderline, it is best to observe the patient at monthly intervals rather than "muddy the water" by beginning treatment. One should remember that since the treatment is lifelong, diagnostic certainty is important.

Funduscopic and visual field examination by confrontation should be done on all patients with apparent primary myxedema. Head x-rays to rule out a pituitary tumor should be obtained.

Before starting thyroid hormone in any patient with primary myxedema, one must inquire carefully about angina and related cardiac disorders and exercise caution in administration if these is present.

Pituitary Myxedema

This condition can be caused by an isolated thyrotropin deficiency, accompanying panhypopituitarism, pituitary dwarfism, or acromegaly. Myxedema may dominate the clinical picture, but one should always inquire and examine for features of hypoadrenocorticism and hypogonadism. A thyroid-stimulating hormone reserve test for the detection of mild secondary hypothyroidism has been described by Studer et al.[11] and is analogous to the use of metopyrone in evaluating pituitary ACTH reserve. In cases of panhypopituitarism, thyroid hormone should be administered along with or after the beginning of adrenocortical replacement therapy. If thyroid extract is given inadvertently before cortisone, there is the danger of precipitating an adrenal crisis.

Hashimoto's Thyroiditis

This is an auto-immune disease primarily of women between the ages of 15 and 40 years. The goiter is usually symmetrical, irregular and rubbery. If the disease is of recent onset, the patient will be euthyroid, but if longstanding, hypothyroidism commonly exists. Laboratory tests usually reveal an elevated sedimentation rate, abnormal zinc or thymol turbidity tests, a protein bound iodine and BEI difference of greater than one, and elevated alpha-2 and gamma globulins on serum protein electrophoresis. If surgery is not indicated, the administration of thyroid hormone suppresses thyroid-stimulating hormone, thereby shrinking the goiter and relieving hypothyroidism if it exists.[12]

Hyperophthalmopathy of Grave's Disease

The severe exophthalmos of Grave's disease is without a doubt the most difficult manifestation to treat successfully. As it can be brought on or aggravated by thyroid surgery, many physicians use thyroid hormone, particularly if the hyperthyroidism is mild. It is thought that thyroid hormone suppresses thyrotropin and exophthalmos-producing substance. Other adjunctive methods of treatment are with Lugol's solution, steroids, diuretics, small doses of roentgen therapy to the retro-orbital tissues and, of late, surgical decompression of the retrobulbar space.[13]

Simple Goiters

Simple goiter is commonly due to hypoiodinism. It is also called endemic goiter, is apt to appear in mountainous regions and is common in the Great Lakes area. These patients are usually euthyroid but occasionally hypothyroidism is found. Simple goiter predisposes to the development of adenomatous goiter, thyrotoxicosis and cancer, and many endocrinologists feel that this and all goiters, unassociated with thyrotoxicosis, should be treated with thyroid hormone indefinitely.

Thyroid Cancer

Thyroid hormone plays an integral part in the treatment of thyroid cancer. Most thyroid cancers and their metastases, except for advanced cases with anaplastic carcinoma, are dependent on thyrotropin for their growth. Thyroid hormone is administered before and/or after surgery to suppress thyrotropin, also serving as replacement therapy if a total thyroidectomy has been done.

In some cases of early papillary carcinoma, thyroid alone is the drug of choice, as advised by many endocrinologists. In follicular carcinoma, if radio-iodine therapy is anticipated following surgery to destroy any remaining tumor, thyrotropin and thyroid hormone are both given. Generally speaking, patients with thyroid cancer need thyroid hormone just short of producing thyrotoxicosis for the remainder of their lives.[14]

If a thyroid nodule does not take up radioactive iodine ("cold nodule") and will not shrink on suppressive thyroid therapy, it should be removed surgically. Thyroid nodules should be watched carefully, since the question whether thyroid carcinoma will shrink under suppressive therapy or metastasize during observation has not been answered.[15]

Summary

This paper has presented a conservative approach to thyroid hormone therapy. Hypothyroidism from several possible causes, the hyperophthalmia of Grave's disease and thyroid cancer are the most common specific indications for its use.

A vast number of conditions are being treated with thyroid hormone despite the absence of definite evidence of hypothyroidism. Thyroid hormone has little benefit in such nonspecific and isolated conditions as obesity, chronic fatigue, deafness, dry skin, menorrhagia or infertility.

On Being a Patient

There was no doubt that having pneumonia had been a stupendous experience; it was almost like being outside the world altogether, or at any rate like being in a world of dream-work so terrific that I afterwards thought of it as a sort of supernatural revelation. Those vague multitudes under enormous flame-lit arches — what could they have been if they were not something to do with death? Even now I can recover my awed sensation of having been away from life, of having had a glimpse of something for which I had no words. — Siegfried Sassoon (1886–)

Discretion keeps us from questioning, delicacy keeps us even from guessing.
— Comtesse Diane

On Longevity

In his Makrobiotik Christoph Hufeland (1762–1836) gives an account of several instances of exceptional longevity. One of these relates to Terentia, the wife of Cicero, who, despite the sore trials to which she was subjected, and despite the occasional attacks of gout with which she was afflicted, attained the great age of 103 . . . Two other Roman women are mentioned by Hufeland as having attained a great age. They were both of them distinguished actresses. The first one, whose name was Luceia, began her theatrical career at a very early age and was 112 years old on the occasion of her last appearance on the stage; her entire theatrical career having covered a period of one hundred years. Galeria Copiala is the name of the other actress, who was at the same time famous as a danseuse. Ninety years after her first appearance on the stage she took part in a complimentary performance in honor of Pompey; and even at a still later date she acted in a play which was intended to celebrate the distinguished reign of the Emperor Augustus.

Hufeland mentions further instances of great longevity which he had gleaned from Jewish history, and from these I select the following: Abraham lived to be 175 years old, and his wife, Sarah, the only woman of that remote period of time of whom we possess a precise knowledge, died at the age of 127; Isaac attained the age of 180; Jacob lived to be 147; Ishmael, a son of Hagar and a man of warlike habits, attained the age of 137; and Joseph, the next to the youngest of Jacob's sons, a political leader and a man of great wisdom, died at the age of 110. Moses, a man of conspicuous intellectual capacity and possessing a strong will, lived to be 120 years old . . . Joshua, who led a very active life and was a good deal of a warrior, died at the age of 110; and Elisha, who despised all the conventionalities of life and cared nothing for wealth, lived far beyond the limit of 100 years.

The Greek philosopher Pythagoras, who recommended care in the choice of one's food, moderation in eating, and the cultivation of gymnastic exercises, attained a good old age. He claimed that after a man reached his eightieth year, no matter how great an age he might afterward attain, he should be reckoned among those who have ceased to live.*

Whatever is agreeable to You, O Universe, is so to me, too. Your operations are never mis-timed. Whatever Your seasons bring is fruit for me, O Nature. From You all things proceed, subsist in You, and return to You. — Marcus Aurelius

Apocrypha

Honour a physician with the honour due unto him for the uses which ye may have of him: for the Lord hath created him. For of the most High cometh healing, and he shall receive honour of the King. The skill of the physician shall lift up his head: and in the sight of great men he shall be in admiration. — Ecclesiasticus

Retroperitoneal Fibrosis:

A Confusing Syndrome*

GORDON W. STROM, M.D.
Minneapolis, Minnesota

RETROPERITONEAL FIBROSIS is an unusual disease of obscure etiology characterized by a retroperitoneal fibrotic plaque causing constriction and loss of function of the involved structures. It may be a self-limited disease and regress; or it may progress and require surgical intervention. Males are more likely to develop the disease than females in a ratio of 3:1. It occurs between the fourth and sixth decades of life. It was a great rarity twenty years ago; but it now is a well-recognized entity.

Etiology

No specific cause of the disease has been found. Factors believed to be implicated have been: sensitivity to an autogenic agent with antibody response; infection spread by lymphatics, vasculitis, and prolonged use of methysergide (Sansert), ergotamine tartrate (Cafergot), and other drugs. The disease was not described adequately before 1948. Subsequently, many new drugs have been introduced which may have contributed to the increased incidence of the disease.

Symptoms

The early phases of the disease when the tissue reaction is first taking place may be without symptoms or cause vague abdominal complaints. As fibrosis and contraction occur during the late or healing stage, the structures within the area are affected and cause symptoms. Constriction of the great vessels may cause intermittent claudication. Edema of the lower extremities and hydrocele occur when the vena cava and spermatic veins are obstructed. Cases have been reported in which biliary and duodenal obstruction occurred. In one case, retroperitoneal fibrosis simulated carcinoma of the pancreas. Vague abdominal and loin pain is a common manifestation. Anemia and weakness are usually present. Oliguria and anuria occur when the disease reaches its most serious phase. Ormond's[2] original classical description is of a middle-aged man with anorexia and backache in whom oliguria and axotemia developed.

---

*Presented at the Monthly Surgical Meeting, The Swedish Hospital, Minneapolis, Minnesota, July 23, 1965.

Diagnosis

Excretion urograms may be diagnostic. Hydronephrosis and hydro-ureter result from constriction of the mid-ureters; however, no difficulty is usually encountered in the retrograde passage of the ureteral catheter. The mid-ureters are displaced toward the midline by fibrous constriction. Lymphangiograms have demonstrated the disease before changes in the urinary system have occurred.

Treatment

When the diagnosis is made, ureteral obstruction can be relieved by ureterolysis. Both ureters can be approached through a long mid-line incision. The right ureter is reached through the posterior peritoneum by mobilizing the ascending colon and duodenum medially. On the left side, the ureter is reached by mobilizing the sigmoid colon. Both ureters can be freed rather easily because there is a good line of cleavage and the ureters are not invaded by the fibrous reaction. They are mobilized laterally and need not be intubated. If the diagnosis is obscure and the kidney approached through the flank, temporary nephrostomy can be employed. The value of steroids has not been clearly demonstrated, as some cases of spontaneous remission have been recorded. In cases of drug allergy, discontinuance of the medication has resulted in regression without the need of surgery.

Pathology

Grossly, the fibrosis is most dense where the ureters cross the iliac vessels and may involve an area from the aortic bifurcation to the renal arteries. The extent and amount of inflammation may vary considerably. Microscopically, there are dense bundles of collagenous tissue with typical connective tissue cells associated with inflammation. In some cases, there has been a resemblance to periarteritis nodosa.

Case Report

A 52-year-old white male crane operator was first seen at The Swedish Hospital in October 1963, at which time his main complaint was right lower quadrant pain of variable duration and intensity for eight to ten years. There was no history of ingestion of drugs. Gallbladder, colon, excretory urograms, upper gastrointestinal, chest, lumbosacral and spine films failed to explain the cause for his discomfort. Routine laboratory studies were normal. It was noted that the sedimentation rate was elevated on two occasions, being recorded as 53 mm. and 57 mm. per hour. The patient was discharged with a diagnosis of functional spastic bowel.

He was readmitted to the hospital in November 1963, with the same complaints. Again it was noted that the sedimentation rate was elevated to 65 mm. per hour. Exploratory laparotomy was entirely negative except that the mesentery to the ilium was thickened, irregular, nodular and somewhat cobblestone on its surface, and there was erythymatous injection in some areas. The mesentery was biopsied and a retrocecal appendix was removed. The biopsy revealed fat with inflammatory margins, and the section of the appendix suggested subsiding appendicitis.

The patient continued to have right lower quadrant pain and always felt below par. On May 25, 1964, he developed right testicular swelling with hydrocele and was readmitted to the hospital three days later with a history of not having passed any urine for 48 hours and having bilateral lumbar pain. On catheterization there was no urine in the

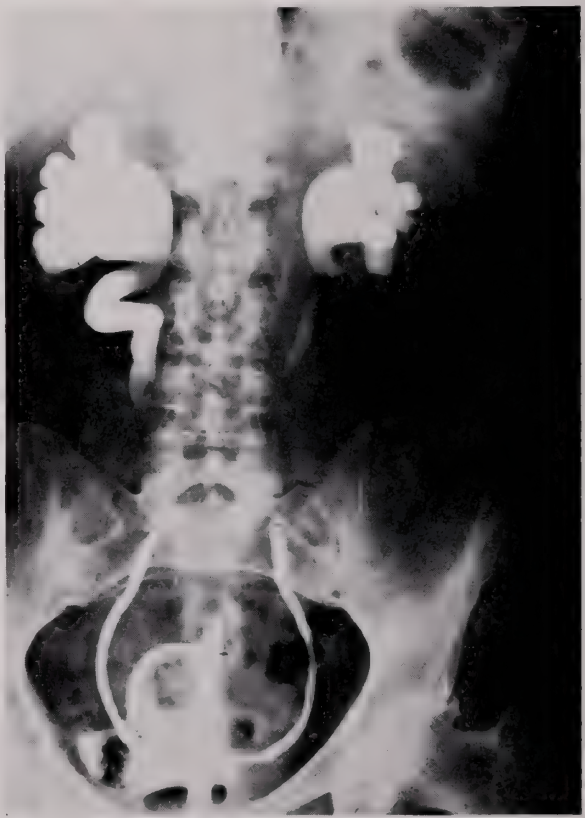

Fig. 1 — Retrograde uretero-pyelogram showing compression and medial displacement of mid-ureter with hydro-ureter and hydronephrosis above.

bladder. The patient was pale and edematous and had an uremic odor to his breath. The blood pressure was 150 systolic and 90 diastolic. Laboratory findings on admission were: wbc. 6,100; normal differential; BUN. 67; Co_2 14.7; chloride 102; sodium 136; potassium 6.2; hemoglobin 9.5; and red blood cells 3,380,000. The following day, the blood urea nitrogen was 97 mgm. per cent. A small amount of urine was obtained which revealed packed red blood cells, pus cells and a 4-plus albumin. The patient was then cystoscoped, and under local anesthesia #4 catheters were passed up each ureter to the renal pelves without meeting any resistance. They drained immediately with a copious rapid drip of dilute urine. The catheters were left in place as it was obvious that the patient had a bilateral hydronephrosis. Bilateral retrograde pyelograms revealed both mid-ureters were compressed and both ureters deviated toward the midline with a moderate degree of hydro-ureter of the proximinal ureters and hydronephrosis bilaterally.

The next day the blood urea nitrogen fell to 49 mgm. per cent; two days later it was down to 27 mgm. per cent. The patient was then re-explored under general anesthesia through a long mid-line incision. There was a mass of fixed, hard, white, woody fibrous tissue extending upward from the sacral promontory to the first lumbar vertebra and laterally to the tips of the transverse processes which included the great vessels and mid-ureters. These structures were completely encased in fibrous material and could not be identified. Both ureters were included in the mass for 2½ inches. Below the mass the ureters were of normal caliber; above the mass they were dilated and freely movable. Both ureters were freed easily and mobilized laterally away from the fibrous mass. The remaining defect was obliterated by approximating retroperitoneal fat and peritoneum.

Histologic study of the biopsy specimen showed fibrofatty tissue with extensive chronic inflammatory change. The tissue was heavily infiltrated by numerous lymphocytes, a few neutrophilic and eosinophils, plasma cells, and mononuclear cells, There was no evidence of caseation or malignancy.

Progress

The patient lost 26 pounds while he was in the hospital, much of it fluid. The postoperative course presented no problems and the patient was discharged on the seventh postoperative day. One year later he said that he still had vague lower right quadrant discomfort at times. On excretory urography both kidneys functioned well on the five-minute film. The mid-ureters were displaced laterally as a result of the surgical ureterolysis.

Summary and Conclusion

The etiology of retroperitoneal fibrosis is unknown, but accumulating evidence would indicate that it is probably an immune reaction of collagen tissues. Although drugs and chemicals may be implicated, the cause in most cases remains obscure. The syndrome is confusing and may mimic several abdominal disease conditions until the final stage of bilateral ureteral obstruction occurs. The x-ray and cystoscopic findings are then rather typical. The disease can be alleviated by ureterolysis.

Except for the Common Cold

I should feel myself ungrateful if I did not testify to my enormous respect and gratitude to the medical profession, and really, on the whole, the doctors I have known have been, I think, among the finest men of my acquaintance. I may have been very fortunate, but that has been my experience. And I am thinking not only of their skill — though I think I should think even more of them if they had discovered how to prevent and how to cure a common cold — but also I have found them always the kindest and wisest friends. And I cannot speak too highly of their wonderful generosity in money matters, a generosity far surpassing what I have found in any other profession. — Dean Inge: Address to Students of the London Hospital, 1933.

The Theriac Cure-All*

The most called-for remedy in all the countries at the time of Harvey . . . was the famous theriacum** or theriac, a remedy as old as Galen, probably older, and which has undoubtedly made more "cures" than any other drug compilation. Even in Galen's time, the prescription for it was extremely complex and a little bit later it came to be spoken of as a "calendar" prescription because it had as many or more ingredients in it than the days of the month . . . It was a veritable gunshot prescription with the shot so scattering that it was sure to hit something, provided it was sent anywhere near the general direction of the object at which it was aimed.

Claude Bernard, the great French physiologist, has told the comical story of it. As a boy he worked in a drug store. He found there was one remedy that was sold more than any other in this small town in western France. This was the theriac. It was kept in a great big jug and the bottles of those who brought in their own were filled with it, or other bottles were supplied to customers for a consideration.

It was a cure for colds as well as for indigestion, for the various bronchitises as well as for heart trouble, for depression and nervousness, for both mind and body. The druggist boy who sold so much of it felt that the whole mystery of medicine was contained in this one remedy. Soon in the round of his duties as a nascent pharmacist he found the secret of it. All the spoiled medicines in the store went into the theriac jug. Whenever a mistake was made in compounding a prescription it was poured into the jug. Whenever there was a drug preparation left standing so long that there might be a reasonable suspicion that the strength of it had either diminished or increased until they did not care to dispense it in the regular fashion, that, too, went into the jug. When by some chance a label came off a bottle and it was not quite sure what was in it the rule of the store was: "Dump it into the theriac jug." Fortunately all the really active ingredients were so diluted that the resulting compound was not likely to do harm, and it is easy to understand that this hodge-podge of drugs of all kinds had a thoroughgoing mediciny taste and was sufficiently nauseous to make even the most hardened veteran taker of drugs feel that he was getting something for his money.

The Unwritten Law

Of course everybody knows that Doctors never say anything unkind about each other, it is part of their Unwritten Law and a sore trial to nearly all of them. The only person to whom a Doctor can say exactly what he thinks about another Doctor is his Wife. That is why practically all Doctors are married. — Joyce Dennys: The Over-Dose.

Of a sane man there is only one safe definition: he is a man who can have tragedy in his heart and comedy in his head.— Chesterton

Partial Anomalous Pulmonary Venous Return

A Hypoplastic Right Lung to the Inferior Vena Cava (Scimitar Syndrome*)

EARL G. YONEHIRO, M.D., Ph.D.**
St. Louis Park, Minnesota
GRADY L. HALLMAN, M.D.†
DENTON A. COOLEY, M.D.†
Houston, Texas

Anomalous venous connection between the right lung and the inferior vena cava is a rare congenital defect which is often associated with abnormalities of the bronchovascular structure of the right lung. Oxygenated blood from the lung enters the right heart through the inferior vena cava resulting in a left-to-right shunt with its deleterious effects. Pulmonary venous return may be routed to the left atrium by a closed extracardiac operation, but cardiopulmonary bypass is often required. Anomalies of the right lung may be dealt with as indicated at the same operation. Recent experience with the successful surgical treatment of a patient with anomalous connection between the venous drainage of the right lung and the inferior vena cava prompted us to make this report.

Case Report

A six-year-old Puerto Rican girl was admitted to the Texas Children's Hospital on November 16, 1964, with a two-year history of easy fatigability and recurrent bouts of palpitation with rapid heart action.

When the patient was seven months old, the parents were informed that she had a heart murmur; when she was three years old a diagnosis of patent ductus arteriosus was made by a cardiologist. The child developed slowly for her age and sustained numerous pulmonary infections, some of which required hospitalization for treatment.

In 1962, at four years of age, the child underwent division and suture of a patent ductus arteriosus. At that time a "vascular ring" was interrupted by dividing a retro-esophageal right subclavian artery. The following year in Puerto Rico cardiac catheterization demonstrated an anomalous venous return of the right lung into the infradiaphragmatic portion of the inferior vena cava. In addition a stenosis was noted at the junction of the inferior vena cava and the right atrium, causing collateral flow through the azygos system. Multiple stenoses of the peripheral pulmonary arteries were also demonstrated.

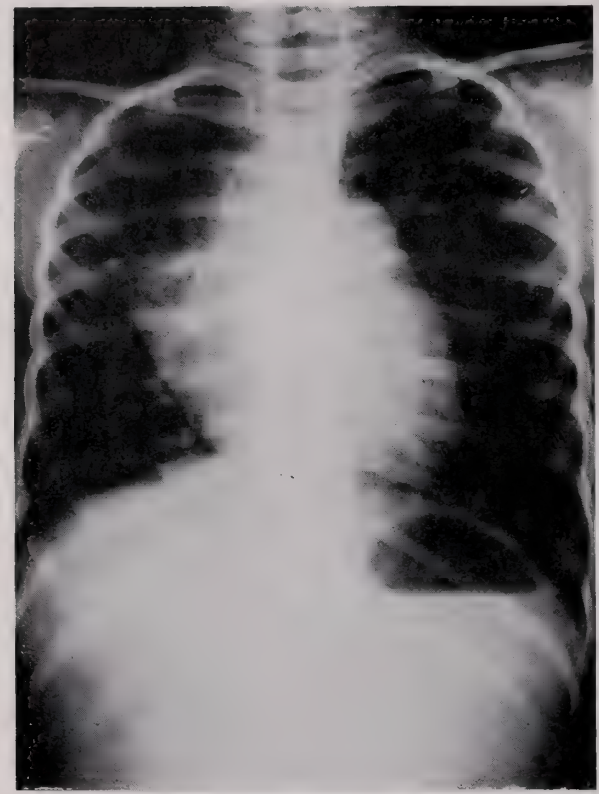

Fig. 1 — Anteroposterior roentgenogram of chest showing scimitar-shaped shadow along right border of heart.

Physical Findings

On physical examination the blood pressure was 100/68 in the left arm and the pulse rate was 90 (regular). No pulses were present in the right arm. Her height and weight (36 pounds) placed her in the twenty-fifth percentile on the anthropometric chart. Examination of the heart revealed gross enlargement. There was a Grade IV continuous murmur over the left axilla and adjacent left posterior chest, with a greatly accentuated split-second heart sound. The lungs were clear to percussion and auscultation. There was no clubbing of the digits and no peripheral edema.

Laboratory Studies

An electrocardiogram demonstrated right ventricular hypertrophy and first degree A-V block. Laboratory data included a white blood cell count of 8,100, a normal urinalysis, a hemoglobin of 13.3 gm. per cent, a hematocrit of 41 per cent, and a blood urea nitrogen of 8 mg. per cent. Roentgenograms of the chest disclosed moderate cardiac enlargement with increased pulmonary vascularity. A crescent-shaped shadow was present along the right border of the heart (Figure 1).

Cardiac Catheterization Studies

Cardiac catheterization revealed an oxygen saturation of 95 per cent in the inferior vena cava near the diaphragm. Pressure in the main pulmonary artery was 72/35 mm. Hg., while the systemic pressure was 136/78 mm. Hg. The catheter was passed up the inferior vena cava into an anomalous venous trunk draining the right lung. A pressure gradient of 28 mm. Hg. was recorded between this trunk and

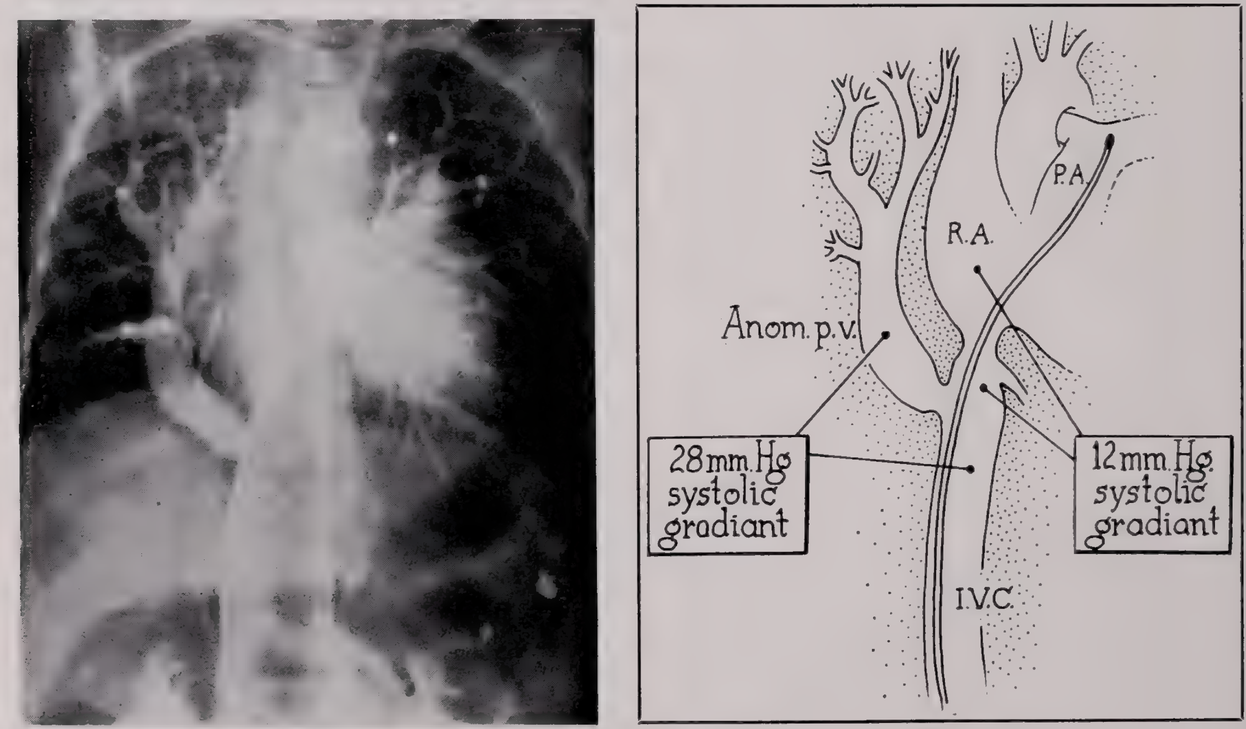

Fig. 2-a

Fig. 2-b

Fig. 2 — a. (left) Angiocardiogram with catheter in pulmonary artery. Note large vein draining entire right lung and traversing diaphragm to enter inferior vena cava. b. (right) Drawing of a. showing anatomy of veins and gradients present.

the inferior vena cava below the hepatic veins. A second pressure gradient of 12 mm. Hg. existed between the inferior vena cava near the diaphragm and the right atrium. Angiocardiography was performed by injecting contrast medium into the pulmonary artery. The pulmonary veins from the right lung converged in a large trunk that descended along the right border of the heart and narrowed just before it entered the inferior cava below the diaphragm (Figure 2). Enlarged azygous and hemiazygous veins were seen to serve as collateral pathways to carry pulmonary and systemic venous blood around the partially obstructed inferior vena cava into the superior vena cava. The oxygen saturation of blood at the junction of the superior vena cava and azygous vein was 90 per cent.

The Operation

An operation was performed on November 23, 1964. The patient was placed in the supine position with the right side elevated 45 degrees. A transverse incision was made in the right fourth interspace transecting the sternum but not entering the left pleural space. Exploration revealed that the pulmonary veins of the right lung converged into a single trunk approximately 12 mm. in diameter that descended between the heart and lung to pierce the diaphragm. Compensatory dilatation of the azygos vein, inferior vena cava, and the right atrium was present. The right lower lobe was enclosed in a separate pleural envelope and was supplied by a systemic artery entering its lower surface through the diaphragm. The middle lobe was normal.

After mobilization it was apparent that the anomalous pulmonary vein was not sufficiently long to permit an anastomosis between it and the left atrium without undue tension or kinking. Consequently, the vein was divided near the diaphragm and anastomosed end-to-side to the right atrium near the septum. An intracardiac diversion was then performed with cardiopulmonary bypass using a disposable plastic bubble oxygenator primed with 5% dextrose in water. A longitudinal incision in the right atrium allowed visualization of the anastomosis on the posterior wall of the right atrium near an intact septum. A small portion of septum, 1.5 cm. in diameter, was excised posteriorly near the anastomosis. An oval patch of pericardium sutured to the superior, anterior, and inferior margins of this aperture and then to the posterior wall of the right atrium to the right of the anastomosis permitted blood to be channeled from the right pulmonary vein into the left atrium. The right atrium was closed and cardiopulmonary bypass discontinued (Figure 3). After resumption of satisfactory cardiac action, the sequestered right lower lobe was removed. The patient had an uneventful postoperative course and was discharged ten days following operation. She was re-evaluated nine months after operation and was asymptomatic. Cardiac catheterization at that time revealed moderate pulmonary hypertension (62/30 mm. Hg.) and no shunt.

Examination of the pulmonary tissue showed an aberrant position of the vessels along the hilar aspect of the right lower lobe. Many of the pulmonary arteries were of diminished caliber and there was intimal fibrosis and disruption of elastic fibers in the media. Large and small pulmonary veins exhibited moderate increase in thickness of their walls, and intimal sclerosis was present.

Discussion

In a classic review of 100 cases of anomalous pulmonary venous return published in 1942, Brody[4] found only three patients with abnormal drainage from the right lung into the inferior vena cava. Since the advent of angiocardiography, several excellent articles have appeared on this subject.[1,10,11,12,14,17,23,29] Interest in anomalous pulmonary venous drainage has mounted with the development of methods for accurate clinical and laboratory diagnosis, since corrective surgery is now possible.

X-ray Findings

The "scimitar syndrome" is a descriptive term applied by Neill[23] to a condition that originally included a hypoplastic right lung with a systemic arterial supply and venous

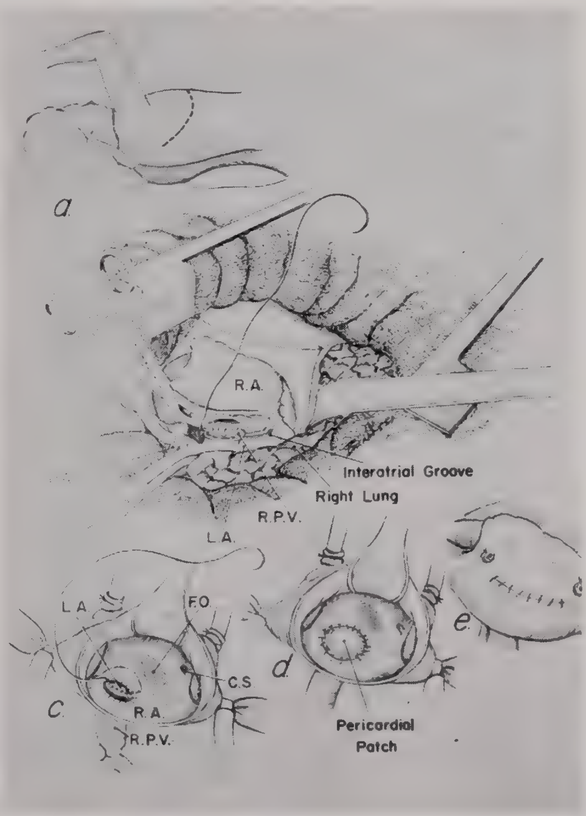

Fig. 3 — Artist's illustration of operative procedure with creation of interatrial septal defect, shunting blood returning from the right pulmonary vein to the right atrium and through the septum into the left atrium.

TABLE
Surgical Treatment of Patients with Scimitar Syndrome

Authors	Age Yrs.	Sex	Add. Venous Drainage	Assoc. Heart Defects	Assoc. Rt. Lung Defects	Procedure	Results and Comments
Drake & Lynch (1950)	14	M	Sup. pulm. v. to lt. atrium	None	No middle lobe	Rt. lower lobectomy w/division of inf. pulmonary vein	Improved, though cough and mild exertional dyspnea persisted
Cooke (1951)	20	M	Sup. pulm. v. to L.A.	None	—	Exp. thoracotomy only	Unchanged

*In addendum author notes three additional patients "Successfully treated" . . . No details given.

drainage into the inferior vena cava. A scimitar-shaped vascular shadow presented a characteristic appearance paralleling the right cardiac silhouette and represented the anomalous pulmonary vein descending to join the inferior vena cava. The diagnosis can usually be entertained on viewing the plain posteroanterior roentgenogram of the chest (Figure 1). The right upper lung field may appear relatively avascular, and the right hemithorax is frequently smaller than the left. Because of these anatomical changes the right atrium is prominent and the heart appears to be shifted towards the right.

Anatomical Anomaly

Often the right lung is a mirror image of the left lung, having no, or only a rudimentary, middle lobe. Hypoplasia of the right lower lobe may be present. Occasionally the right superior pulmonary vein empties normally into the left atrium while one or more of the remaining pulmonary veins form a common trunk that may enter the portal vein or the infra or supradiaphragmatic portion of the inferior vena cava. In this type of partial anomalous pulmonary venous return, arterialized pulmonary venous blood from the right lung recirculates through the right heart instead of passing into the systemic circulation by the normal route through the left heart. Hemodynamically this represents a left-to-right shunt, increases the work load of the heart, and leaves the patient with essentially a functionless right lung. In the present case a stenosis at the junction of the inferior vena cava and the right atrium resulted in augmentation of the collateral flow through the azygous vein. With relative obstruction of the inferior vena cava, the azygous and hemiazygous veins become the principal means by which venous circulation is sustained, connecting as they do with the superior and inferior venae cava. The unique participation of the azygous system in this patient is reflected in the catheterization data which demonstrates blood with increased oxygen content (90 per cent) at the junction of the superior vena cava and azygous vein.

Intracardiac Malformations

The most common intracardiac malformation associated with partial anomalous pulmonary venous connection is an atrial septal defect. Shumacker[27] reports an associated atrial septal defect or stretched foramen ovale in 90 per cent of patients with partial pulmonary venous return to the right atrium or superior vena cava, but in only 11 per cent of such patients with drainage to the inferior vena cava. In patients with findings consistent with an atrial septal defect, Frye and his colleagues[12] emphasized the presence of a split-second heart sound as an important diagnostic clue to the presence of partial anomalous pulmonary venous return. Wide splitting of the second heart sound is frequently described in patients with the scimitar syndrome[17,18,22] and was present in our case.

Pulmonary Abnormalities

Abnormalities such as agenesis or hypoplasia of part of the right lung are also associated with anomalous pulmonary venous drainage from the right lung to the inferior vena cava. Systemic arteries arising from the aorta and supplying the right lung are also found in these individuals. Indeed, Kittle and his associates[17] have described this condition as a "vena cava bronchovascular syndrome" consisting of a triad of anomalies involving the right lung. This triad has (1) anomalous pulmonary venous connection, (2) abnormal bronchi, and (3) systemic pulmonary arteries. Because of the frequency of associated pulmonary abnormalities, bronchoscopy and bronchography may be valuable in the preoperative evaluation of these patients.

Clinical Manifestations

Previous authors[2,11,12,14,21,23,28] have described the benign course in many patients with scimitar syndrome. Certainly many are totally asymptomatic when first seen. O'Brien's[24] three patients all had multiple normal pregnancies, indicating that this condition may produce few cardiac symptoms and may be compatible with survival to adult life. Patients, however, may complain of easy fatigability and dyspnea and may develop recurrent respiratory infections. Although some authors have advised conservative treatment for these patients, an aggressive surgical approach has more recently been advocated.[5,8,16,25,27,28,31] The demonstration of a large pulmonary blood flow and elevation of the pulmonary artery pressure in association with a large left-to-right shunt constitutes a definite indication for surgical intervention. As emphasized by some authors[5,10,12] the prognosis in patients with this condition is probably the same as for a patient with an atrial septal defect as far as hemodynamic changes are concerned. Therefore, operative correction to prevent heart failure and subsequent pulmonary vascular changes should be advocated. The obvious disadvantage of a "functionless" right lung constitutes an additional indication for operative correction. Shumacker[27] advises early surgery in individuals with the vena-cava-bronchovascular syndrome because of the likelihood of pulmonary infection and because of the left-to-right shunt with its attendant hemodynamic disturbance.

Therapy

Resection of pulmonary tissue with normal bronchial supply is neither advisable nor desirable and should be reserved for those cases in which a complete repair is impossible.

Neill,[23] in discussing a patient with scimitar syndrome and severe pulmonary hypertension who had expired following pneumonectomy, felt that the pulmonary artery pressure increased in the remaining lung to a point incompatible with life. Ferencz,[11] in reviewing this article, indicated that the scimitar-shaped pulmonary veins had no etiologic significance in the development of pulmonary hypertension, although the two conditions may coexist. Recently Wiederanders and his associates[32] studied the effects of pulmonary resection on pulmonary artery pressure and found that following thoracotomy and resection of less than one lung, the pulmonary artery pressure was little influenced. Pulmonary artery pressure, however, was frequently markedly elevated after pneumonectomy. They concluded that more than one fourth of the vascular bed must be removed to alter the pressure relationship. Thus, if sufficient pulmonary vascular bed is removed, pulmonary hypertension may develop.

In 1956, Kirklin and his colleagues[16] indicated that it was hazardous to occlude one pulmonary artery in a patient with severe pulmonary hypertension. In the presence of severe pulmonary hypertension they concluded that transplantation of an anomalous pulmonary venous connection was probably unwise, since such a procedure would require temporary pulmonary artery occlusion to prevent pulmonary edema during the period of pulmonary venous occlusion. With the availability of extracorporeal circulation, this consideration should not be a deterrent to operation in patients with scimitar syndrome and pulmonary hypertension.

Since 1950 the surgical treatment of the scimitar syndrome has been reported in only 23 patients (Table). Early surgical attempts were limited to pulmonary resection, especially pneumonectomy. In 1956, Kirklin[16] reported the first complete correction of this condition by transplantation of the anomalous right pulmonary vein to the posterior right atrial wall and diversion of blood into the left atrium by means of a closed atrioseptopexy. Since then only twelve additional cases of total correction have appeared in the literature (Table). Only one death occurred in this latter group; this was a 36-year-old patient who died of postoperative pulmonary complications.

The most effective technique of repair appears to be anastomosis of the anomalous right pulmonary vein to the left atrium wherever possible. If the length of the vessel precludes this, the vein should be anastomosed to the posterior aspect of the right atrium, and blood diverted from this ostium into the left atrium by the insertion of a patch sutured about an opening in the atrial septum (either naturally occurring or surgically created), using cardiopulmonary bypass. Abnormalities of the right lung may be dealt with as indicated.

Conclusion

Anomalous drainage of venous blood from

the right lung into the inferior vena cava occurs by means of a large trunk that forms a crescent-shaped shadow along the right border of the heart. When combined with anomalies of the right lung, the name scimitar syndrome has been applied to this complex. Surgical treatment of this anomaly is reviewed and operation recommended when symptoms become significant.

Profunda Femoris-Popliteal Shunt

Medial Approach

HARRISON H. FARLEY, M.D.
ROBERT L. TELANDER, M.D.
CLAUDE R. HITCHCOCK, M.D., Ph.D.*
Minneapolis, Minnesota

REVASCULARIZATION PROCEDURES in the lower limb for arteriosclerotic occlusion of the superficial femoral artery must be individualized because of variations in the extent of disease found to be present on surgical exploration. Whether the occlusion is corrected by endarterectomy or bypassed with a plastic prosthesis or autogenous vein depends to a degree on the personal preference of the operating surgeon.[1-3] Endarterectomy has proved to be successful, but if it is to be performed over any considerable length of vessel, bits of roughened intima may be left behind with a propensity towards reocclusion. The ready availability of the plastic prosthetics has given great impetus to the growth of peripheral vascular surgery, but long-term follow-up studies[4,5] have revealed a rather high rate of late occlusion. The problems of excessive foreign-body reaction and infection are real and mitigate against the use of prosthetics below the inguinal ligament.

Abstract

There are occasions when a bypass procedure, which has been done to revascularize an arteriosclerotic extremity, fails and reoperation becomes necessary. In the hands of Farley et al. an alternative procedure, wherein the saphenous vein is removed and reimplanted, providing an anastomosis between the profunda femoris and the popliteal arteries avoids the previous surgical procedure by making a medial approach. They have found two advantages to this approach and have encountered no disadvantages.

Editors' Note: This manuscript was published in Minnesota Medicine 49:400, 1966. The title was inadvertently incomplete. Because of the significance of this manuscript the title page is hereby reprinted and an abstract attached.

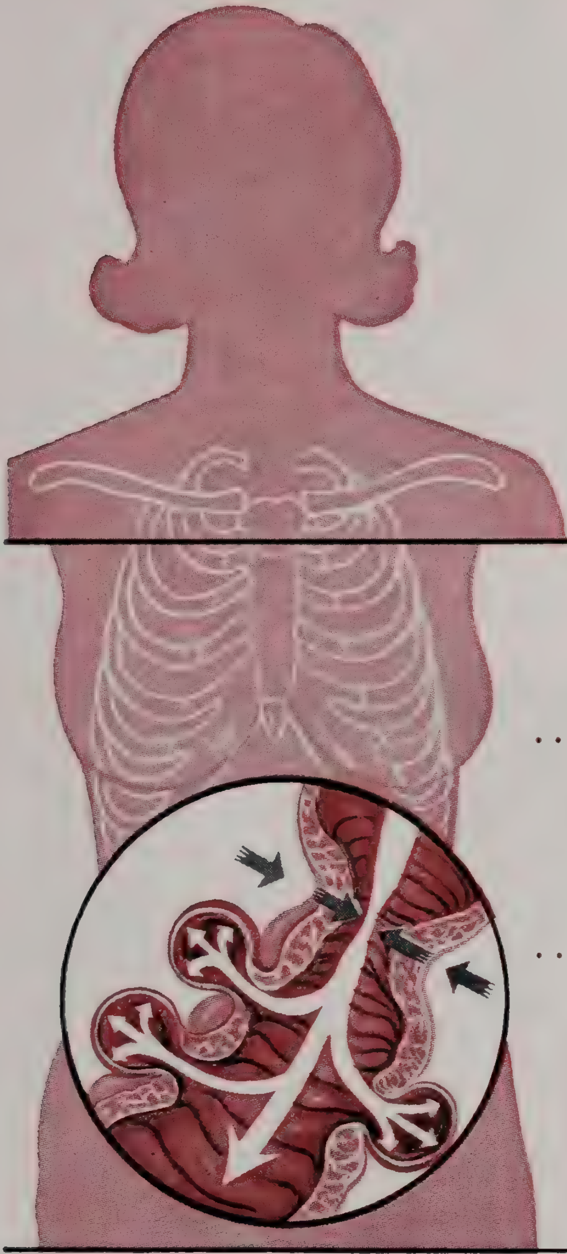
Increased pressure from straining aggravates diverticulitis

METAMUCIL®

brand of psyllium hydrophilic mucilloid

Metamucil Powder: 4, 8 and 16-ounce containers.

Instant Mix Metamucil: cartons of 16 and 30 single-dose packets.



Metamucil

. . . to counteract the constipation which is etiologically important and

. . . to protect the mucosal surface against physical irritants.

Average Adult Dosage:

One rounded teaspoonful of Metamucil (or one packet of Instant Mix Metamucil) in a glass of cool liquid one to three times daily.

SEARLE

Research in the Service of Medicine

Thanks to Dexamyl®

brand of
dextroamphetamine
sulfate and amobarbital

she can say "No thank you" to the crêpes suzette.

'Dexamyl' does more than most anorectics. Because it curbs appetite *and* lifts mood, 'Dexamyl' can encourage the discouraged dieter to stay on her diet.

The mood lift with 'Dexamyl' can make the difference between the success or failure of her diet plan.

Formulas: Each 'Dexamyl' Spansule® Capsule (brand of sustained release capsule) No. 1 contains 10 mg. of Dexedrine® (brand of dextroamphetamine sulfate) and 1 gr. of amobarbital, derivative of barbituric acid [Warning, may be habit forming]. Each 'Dexamyl' *Spansule* capsule No. 2 contains 15 mg. of Dexedrine (brand of dextroamphetamine sulfate) and 1½ gr. of amobarbital [Warning, may be habit forming].

Principal cautions and side effects: Use with caution in patients hypersensitive to sympathomimetics or barbiturates and in coronary or cardiovascular disease or severe hypertension. Insomnia, excitability and increased motor activity are infrequent and ordinarily mild.

Before prescribing, see SK&F product Prescribing Information.

Scimitar Syndrome

"THE SCIMITAR SYNDROME" is a malformation of the heart, lungs, and blood vessels producing a left to right shunt of varying magnitudes. The main feature of the malformation is partial or complete drainage of the right pulmonary veins into the inferior vena cava. Associated malformations may be found as abnormal systemic arterial supply to the right lower lobe; dextrorotation and dextroposition of the heart, hypoplasia of the right lung and pathologic changes in the bronchial tree and parenchyma of the right lung.

A simple anteroposterior film of the chest may be diagnostic, showing the crescent-shaped vascular density adjacent to the right cardiac border which closely resembles a Turkish sword (scimitar).

Park in 1912 described the pathology of the disease and Dotter in 1949 made the first clinical diagnosis of this anomaly. With increasing refinements in diagnosis and potential for surgical cure, reports on this subject have appeared with increasing frequency.

In this issue Yonehiro, Hallman, and Cooley* detailed the highlights of the pathology, hemodynamics and clinical features of lesion and reported a case successfully operated by them after vagaries in diagnosis were overcome.

The surgical alternatives for correction are: closed anastomosis of the aberrant vessel to the left atrium, pulmonary resection removing the shunt, and lastly, anastomosis of the anomalous pulmonary vein to the right atrium with repartitioning of the atria with a pericardial patch as carried out by the authors with cardiopulmonary bypass.

Correction of the shunt without the sacrifice of pulmonary function by pulmonary resection is an ideal goal. Pulmonary resection, however, may be indicated in certain circumstances and has produced satisfying results. With increasing technical skills and refinements in the use of extracorporeal circulation, the excellent results reported will serve to expand the indications for surgical correction.

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown®
(meprobamate)

Indications: Meprobamate is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, meprobamate fosters normal sleep through both its anti-anxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: 'Miltown' (meprobamate) is available in two strengths: 400 mg. scored tablets and 200 mg. coated tablets. 'Meprotabs' (meprobamate) is available as 400 mg. white, coated, unmarked tablets. *Before prescribing, consult package circular.*

Auto-Immune Disease

CURRENT THEORIES on the interrelationships between immunity, auto-immunity, and leukemogenesis owe a great deal to imaginative and inquiring clinical observers. The speculations published in the May issue by Good and his colleagues* developed from a large series of observations originally stimulated by a patient with "acquired agammaglobulinemia" who was studied in 1953. This patient had low levels of immunoglobulins and was severely deficient in immunological reactivity but, paradoxically, had an "auto-immune disease," namely rheumatoid arthritis. He was found to have a mediastinal mass which proved to be a benign thymoma. Intrigued by this extraordinary case, Good and a series of collaborators embarked on a lengthy and continuing series of experiments which have helped to elucidate the role of the thymus in the physiology of immunity. Their data indicate that the thymus is essential to the development of full immunologic competence in the mouse, and also to leukemogenesis in this animal. In the chicken the bursa of Fabricius has similarly been shown to be essential for immunologic maturity and also for leukemogenesis. Both of these organs appear to be "source" tissues capable of directing the development of the "peripheral" lymphoid tissue. Good suggests that there may be two lymphoid systems in higher mammals, one directed by the thymus and another directed by an organ analagous to the chicken bursa, which may be located in the appendix, as in the rabbit, or at some other site. They postulate that the thymic system is primarily concerned with immunologic recognition, while the "bursa" system controls production of the various immunoglobulins.

Numerous observations have been recorded from both experimental studies and human disease which suggest involvement of the thymus in the development of auto-immunity. For example, thymic abnormalities have been recorded in lupus erythematosus and myasthenia gravis. Several laboratory examples are also cited by Good. Perhaps the most intriguing is the development of red cells coated with globulin (Coombs-positive) in rabbits which are thymectomized and appendectomized at birth. Some of these rabbits have also developed amyloid disease and other lesions usually attributed to immunologic processes, despite the fact that the animals have become immunological cripples as a result of the surgical procedures. The exact mechanisms which produce this series of events have yet to be worked out. Obviously, the problems involved are important and challenging ones which will probably have a major bearing on both auto-immune disease and leukemia in man.

The Minneapolis group has approached the problems of auto-immunity and leukemia from the background of work on the thymus. It is of interest that other workers have also suggested relationships between leukemia and auto-immunization before the unifying role of the thymus was appreciated. Dameshek and Schwartz in 1959,[1] with the background of years of clinical observation of patients particularly with lymphoproliferative disorders, auto-immune hemolytic anemia and ITP, indicated many points of similarity between leukemia and auto-immunization. They suggested that in both types of disease some change occurs in the growth habits of certain white cell tissues, leading to a proliferation of abnormal cells, and speculated that repeated aberrant immunologic responses might eventually give rise to neoplastic proliferations. The occurrence of immunologic abnormalities in patients with lymphoproliferative disorders is well known. It has been observed that in many patients with chronic lymphocytic leukemia or lymphosarcoma, ionizing radiation or alkylating agents can act as "trigger mechanisms," initiating the development of auto-immune complications such as hemolytic anemia, thrombocytopenic purpura, or vasculitis.[2] These patients are frequently deficient in many of the normal immunologic responses. Thus, there may well be analogies between such patients and Good's adult rabbits which, after thymectomy, appendectomy and irradiation, devel-

*See Minnesota Med 49:725, 1966.

Frankly, most antihypertensives are pretty good if you give an adequate dose. I'm looking for one with a simple regimen so that mix-ups in doses and therefore the chance of side effects are minimized.

Regroton®

chlorthalidone 50 mg. reserpine 0.25 mg.

1 tablet daily brings pressure down

Advantage: Both components of Regroton are long-acting.
Average dosage: One tablet daily with breakfast.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: Discontinue 2 weeks before general anesthesia, 1 week before electroshock therapy, and if depression or peptic ulcer occurs. With administration of enteric-coated potassium supplements, the possibility of small bowel lesions should be kept in mind.
Precautions: Reduce dosage of concomitant antihypertensive agents by one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.
Availability: Bottles of 100 and 1000 tablets.

Geigy

oped Coombs-positive hemolytic anemia and other manifestations of auto-immune disease. Multiple myeloma, macroglobulinemia, and Hodgkin's disease, are other disorders which appear to manifest a spectrum of combined leukemic and immunologic proliferation and immunologic deficiency.

There are many pitfalls in the interpretation of data on auto-immune disease. Several forms of immunologic purpura have been shown to be due not to auto-antibodies to platelets, but to antibody to drugs or to foreign platelet antigens. Similarly, although a positive Coombs test is frequently taken as evidence of auto-immunity, several cases of Coombs positive hemolytic anemia have been reported which were due to antibodies directed not to the red cells, but rather to penicillin administered to the patient. Good's suggestion that auto-immune disease may be due to virus or mycoplasma infection occurring in the setting of immunologic deficiency is an intriguing one, but these infections remain to be demonstrated.

Hip Subluxation in Early Infancy

It is certainly true that treatment of congenital hip in the infant is highly dependent on early recognition. Results are far superior when treatment is instituted within the first several months of life. Congenital dysplasia of the hip, in general, is managed easily; and excellent results can be expected, provided early use of the pillow splint is instituted. Congenital dislocation of the hip, on the other hand, carries a more guarded outlook, although it must still be recognized and treated as early as possible, since best results depend on this.

Ortolani's sign is unreliable within the first two weeks of the newborn period, when the infant is still under the influence of maternal hormones and many falsely positive clicks can be elicited. Limited abduction of the flexed hip is the most reliable sign in the newborn child to indicate the need for radiographic examination.

Preliminary traction is important before closed reduction is attempted. The traction should be continued for several weeks to allow the capsular structures to stretch out gradually so as to reduce the possibility of the development of avascular necrosis in the capital femoral epiphysis. This well-known complication is related to the forcefulness of attempts at reduction and to the failure to use preliminary traction. The report of only one case of avascular necrosis in 19 dislocations attests to the relatively gentle reductions accomplished by Gustilo and co-workers.[1] The proper position for holding patients after closed reduction is the position of maximal stability, as determined clinically and radiographically. This may be the frog-leg position, but often the Lange position (internal rotation and abduction of the leg) is better initially, especially when marked anteversion of the femoral neck is observed.

If closed reduction is not possible, open reduction is carried out, when, generally, the position of best stability is found to be that of internal rotation. Excessive anteversion of the femoral neck is best managed by derotational osteotomies which probably should be performed more often than they currently are.

Detection and Localization of Intracranial Lesions

THE RELIABLE detection, by means of remote or external sensing devices, of physical or chemical substances concentrated in an intracranial pathologic process has intrigued investigators for many years. It is now apparent that certain radioactive isotopes can be chemically combined with compounds which, under certain circumstances, will become concentrated in detectable amounts within some of these lesions. One of the most useful of these isotopes is 197-Hg when tagged to Neohydrin. Its value is indicated by the report of Wigdahl, Gilson, Staab, and Loken.* Such developments have been accompanied by improvements in technique so that the procedure has considerable reliability in the detection of neoplastic and non-neoplastic diseases.

In considering these new and exciting procedures, it is tempting to speculate concerning the comparative value of the various techniques designed to reveal intracranial lesions. In the years between the advent of intracranial pneumography and cerebral angiography, opinions concerning the relative merits of pneumoencephalography and ventriculography were subjects of great interest in published reports, professional meetings, and informal discussions. Equally competent investigators preferred one over the other, although there were always certain instances in which one procedure was obviously more suitable. After its general acceptance, cerebral angiography frequently appeared to be in competition with air-contrast examinations, although in many instances the problems could be solved by several of the different techniques. The indications for the most suitable method of initial investigation, however, depend on many factors, including the reliability of the examination and the elements affecting the safety and well-being of the patient. Thus, these procedures are not mutually exclusive.

The development of a reliable brain-scan technique adds another important diagnostic method. It is tempting to hope that, because of its simplicity and usually innocuous effects, it might frequently take the place of more complicated procedures. Unfortunately, like the others, it is not 100% reliable and its execution is rather time-consuming Although considerable statistical information reveals that a positive result of a successfully planned and accurately performed brain scan may indicate the presence of an intracranial pathologic process, a study yielding a negative result, like any other type of examination giving a negative result, does not prove the absence of a lesion. Thus, in the presence of appropriate clinical signs and symptoms, it may be necessary to employ several, if not all, of the available methods before tentatively excluding a pathologic process.

If a lesion can be detected and localized with assurance, such specialized examinations have fulfilled their most important functions. However, the exact nature of several important types of intracranial diseases can be ascertained with considerable accuracy by the judicious application of the appropriate test. This is particularly true of the revelation of aneurysms, A-V malformations, and subdural hematomas by cerebral angiography and of the detection of the size, shape, and position of certain intracranial tumors by means of cerebral pneumography. Therefore, although the brain scan and certain ultrasonic techniques are exceedingly useful methods for the detection and localization of some intracranial lesions, they should not be considered in competition with one another or as mutually exclusive in their application. The physicians in charge are required to select in each instance the test or tests which might be expected to be of most value in the total management of the patient's problem.

Marquette Bank

The MEDAC System

Automated
Bookkeeping
and Billing
by Computer

We promised you'd hear a lot from us this year! Now Marquette Bank offers Twin City Area Doctors and Dentists an exclusive new service—instantaneous, accurate bookkeeping and billing by computer . . . easy to operate.

The Medac system is based on extensive research among scores of doctors and is now in use from coast to coast. Medac creates new profits by reducing your day to day work load of record keeping, assures prompt and accurate billing each month, gives assistance in collection problems by monthly "aging" of your receivables, speeds cash flow, and furnishes many other internal controls that save you time and money.

A compact IBM transmitter in your office connects you to a multi-million dollar computer center through your telephone. It takes only 15 minutes a day to transmit daily transactions of an average size practice.

Changeover in your system can be accomplished quickly and easily with no interruption of billing. And the cost is surprisingly low.

For additional information or a personal demonstration, call 333-5411 and ask for Phil Manthey.

Discovering Small Bowel Tumors

An article appearing in the April issue* of this journal presents the ten-year collected experience of two Minneapolis hospitals with 32 small bowel tumors. The small number of lesions is in keeping with the low rate of occurrence reported in the world literature.

The low incidence may be an important contributing factor to many of the problems of diagnosis and treatment, primarily because the experience of any individual physician is limited. The early symptoms are usually of a relatively nonspecific nature and are frequently attributed to more common and less dangerous gastrointestinal lesions. Nonspecific therapy is most often prescribed and more extensive diagnostic procedures postponed. While delay is of no great importance in dealing with benign lesions, there is no doubt it may influence the salvage rate where malignant lesions are encountered. All too frequently when symptoms become severe enough to warrant abdominal exploration, the surgeon finds that lymph nodes are involved and peritoneal spread has occurred.

The low survival rate in adenocarcinoma of the small bowel is in keeping with the results of therapy for adenocarcinoma of other nearby organs, namely the pancreas and stomach. The failure of therapy in these instances is directly related to the inability of the physician to make a diagnosis at a time when there is any hope of cure. This deficiency is obviously most marked in carcinoma of the pancreas where the diagnostic dilemma has remained essentially unchanged since the introduction of a definitive radical operation. Despite vigorous application of available diagnostic techniques curable tumors of the pancreas are only rarely detected. This is obviously not as true for small bowel carcinomas.

Minor symptoms such as anemia, pain, weight loss seldom bring a patient to early exploration. In fact, many patients with symptoms and negative physical and laboratory findings, may be classed as psychoneurotics and therapy held in abeyance for a period of months or years. An absolute finding such as an abdominal mass or unrelenting obstruction or profound anemia will usually bring the patient to exploration. In these circircumstances, however, the situation may already be irretrievable.

The surest way to swing most physicians and surgeons from procrastination to action is demonstration of the lesion. In order to accomplish this short of exploration, the medical profession has come to rely almost exclusively on radiological examination. However, the efficiency of roentgenologic diagnosis of small bowel lesions decreases from the duodenum to the jejunum and ileum for the most part because of the length and pliability of the small intestine and the unavoidable overlap of its different portions. Furthermore, the technique of examination is seldom mastered, due to infrequent utilization and because intestinal follow-through series as now practiced provide only intermittent film views of the passage of the barium meal.

In order to obtain continuous filling of the small bowel under direct observation so that added information concerning motility, mucosal pattern, and distendability are available, various modifications of the technique have been proposed, most requiring small intestinal intubation (Schatzki, Blodgett, Hodges, Golden & Dundon). This technique permits the use of dilute barium and allows small segments of the intestine to be filled for more detailed examination. Where the intestine has normal motility a Miller-Abbott tube is best passed by the physician or surgeon on the ward before the patient is taken for x-ray examination. The foregoing techniques enable the roentgenologist to obtain greater contrast at the site of examination and afford a better chance of detecting small or intramural lesions.

Furthermore, it has been reported that while primary carcinomas may involve any portion of the small intestine, they show a predilection for the proximal quarter of the jejunum and the distal quarter of the ileum

(Maingot, Kiefer, Dockerty). This fortuitous distribution of lesions should decrease the difficulty and time involved in demonstrating lesions of the proximal jejunum. However, passing a long tube to the distal ileum is a much less practical proposition, and perhaps a greater emphasis should be placed on examination of the distal small bowel by reflux of barium through the ileocecal valve. In fact this occurs relatively frequently during the course of barium enema examination. It has been a common belief that the routine examination of the distal bowel by barium reflux is not only difficult but often impossible due to a competent ileocecal valve present in approximately two thirds of patients. A recent report (Miller & Miller) seems to refute this concept in that a complete examination of the small intestine has been achieved by this procedure, including the proximal jejunum and duodenum in 72 of 75 patients where the examination was attempted. The technique offers the advantages of a barium enema examination of the colon, in that the barium column advances under fluoroscopic observation, permitting the accurate localization of various lesions and the interpretation of mucosal and motility patterns.

A new technique has recently been proposed for the detection of bleeding sites in the stomach or small intestine (Margulis, Baum). It consists of selective catheterization of the celiac or superior mesenteric arteries with injection of contrast media which subsequently appear in the bowel lumen at the bleeding site. Some successes have been reported in the diagnosis of small bowel lesions both in the experimental laboratory and clinical situations. At least for the time being this technique will be limited to large hospital centers.

The problem of the diagnosis and treatment of small bowel carcinomas remains, for the most part, unsolved at the present time. Without question, early diagnosis would increase the salvage rate and allow the fullest use of the radical surgical procedures available at the present time.

Unsuspected Aortoiliac Arterial Occlusive Disease*

PATIENTS WITH the classical findings of the Leriche syndrome present little difficulty in clinical diagnosis, and operation is usually clearly indicated. Those with incomplete occlusion of the aortoiliac arterial segments may have unsuspected impairment of the blood flow to the hips and lower extremities. Symptoms may not always be the typical effort-claudication but may be described as weakness or paresthesias of the hips, thighs, legs, or feet. The presence of palpable pulses throughout the extremity may be misleading because palpable pulses can occur in the presence of impairment of flow. Exercise will frequently produce a reduction or disappearance of the pulses in such cases. The presence of a bruit over the terminal aorta or iliac or femoral artery is highly suggestive of a stenotic lesion in the region.

Translumbar aortography is indicated in all cases in which there is a suspicion of occlusive vascular disease and in which the symptoms warrant investigation.

Surgical treatment for aortoiliac occlusive disease is effective, and the risk can be quite low. Thus, its application seems justified in most patients who are symptomatic. A bypass grafting procedure has many advantages over endarterectomy but has the disadvantage of introducing a foreign substance.

Unsuspected aortoiliac disease is frequently a cause of failure in the surgical treatment of femoropopliteal occlusive disease because of inadequate inflow into a bypass graft or endarterectomized femoropopliteal segment. Disease in these two regions frequently occurs concomitantly, and it is essential that proximal disease not be overlooked when planning an operation on a distal segment. In many cases, correction of the proximal disease will obviate the need for operation in the distal segment.

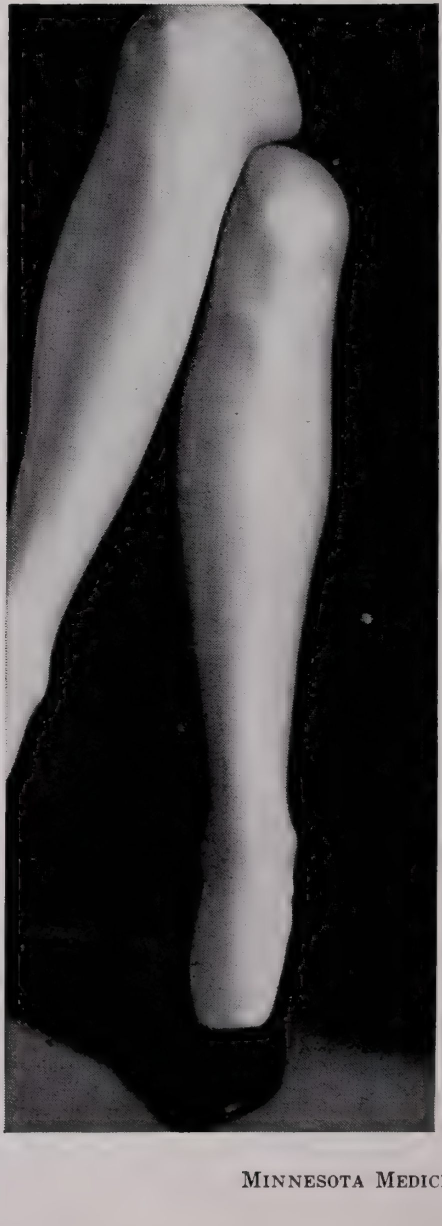
If you can't alarm her
into wearing elastic stockings...

charm her with Ultreer™



You see, a woman simply has no defense against Ultreer Elastic Stockings. They look like lovely support stockings. They feel like lovely support stockings. They're that sheer, and shapely and comfortable.

But that's where the similarities end. New Ultreer fits firmly and evenly over the entire leg. Gives true therapeutic compression necessary to relieve varicose veins and other leg disorders. Each pair provides the therapy you prescribe. And at such a low price, a woman can afford two pairs of Ultreer as easily as she can afford one pair of ordinary elastic hosiery.

Ultreer. What a stocking.

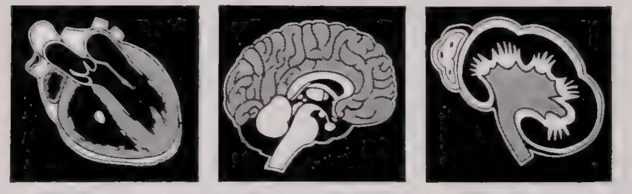
SQUIBB NOTES ON THERAPY

Behind continued high blood pressure readings lies the possibility of organic damage[1-13]

MANY OF THE aspects of essential hypertension are unpredictable—either because there are a number of mechanisms involved or because individuals differ in their responses to these mechanisms.[1]

There is one aspect of hypertension, however, that seems, in many cases, predictable. ". . . when the blood pressure is elevated to a marked degree for an adequate period of time, this in itself leads to perpetuation of the syndrome with resulting vascular damage throughout the body."[14] All too often the disease progresses until there is damage to one of three vital organs: the heart, the kidney, the brain.



> "Hypertension is certainly a major factor in the genesis of coronary heart disease, and it is even more important when compounded with obesity."[4]
>
> "[Vascular deterioration] can be clearly seen in the kidney with a degree of damage that can be measured by renal function studies."[10]

". . . most evidence suggests that reduction of blood pressure, when it is too high, not only relieves the heart of excess work but reduces vascular damage."[1]

"In short, treatment is indicated."[1]

Antihypertensive therapy will not restore the blood vessels to normal. Yet many of the vascular changes and symptoms caused by increased blood pressure may be arrested or alleviated when the blood pressure is reduced to normotensive levels.[7]

Reducing the blood pressure helps curtail further vascular damage and improves the prognosis — when damage is not too far advanced before therapy is started.[14] Essential hypertension is an indication not only for treatment, but for *early* and adequate treatment of the patient in question.

Reduce the blood pressure with Rautrax-N

Rautrax-N combines the antihypertensive-tranquilizing action of whole root rauwolfia with the antihypertensive-diuretic action of bendroflumethiazide in one convenient medication. The two drugs complement each other so that smaller doses of both are possible.

Rauwolfia combined with bendroflumethiazide is particularly effective in long-term therapy,[15-17] since beneficial effects do not diminish with continuous daily administration.

For most patients 1 or 2 Rautrax-N tablets daily are sufficient for maintenance therapy. The simplicity, convenience and economy of such a dosage schedule are of particular benefit to older patients.

Contraindications: Severe renal impairment or previous hypersensitivity. **Warning:** Ulcerative small bowel lesions have occurred with potassium-containing thiazide preparations or with enteric-coated potassium salts supplementally. Stop medication if abdominal pain, distension, nausea, vomiting or G.I. bleeding occur.

Precautions and Side Effects: The dose of ganglionic blocking agents, veratrum or hydralazine when used concomitantly must be reduced by at least 50% to avoid orthostatic hypotension. Caution is indicated in patients with depression, suicidal tendencies, peptic ulcer; electrolyte disturbances are possible in cirrhotic or digitalized patients. Marked hypotension during surgery is possible; consider discontinuing two weeks prior to elective surgery and observe patients closely during emergency surgery. Rauwolfia preparations may cause reversible extrapyramidal symptoms and emotional depression, diarrhea, weight gain, edema, drowsiness may occur. Bendroflumethiazide may cause increases in serum uric acid, unmask diabetes, increase glycemia and glycosuria in diabetic patients, and may cause hypochloremic alkalosis, hypokalemia; cramps, pruritus, paresthesias, rashes may occur.

Dosage and Supply: Initial dosage, 1 to 4 tablets daily, preferably at mealtime. Maintenance, 1 or 2 tablets daily. Rautrax-N is supplied as capsule-shaped tablets containing 50 mg. Rauwolfia serpentina whole root (Raudixin®), 4 mg. bendroflumethiazide (Naturetin®), 400 mg. potassium chloride.

Also available: Rautrax-N Modified — capsule-shaped tablets containing 50 mg. Rauwolfia serpentina whole root (Raudixin), 2 mg. bendroflumethiazide (Naturetin), 400 mg. potassium chloride. Both potencies available in bottles of 100. For full information, see Product Brief.

RAUTRAX®-N

Squibb Rauwolfia Serpentina Whole Root (50 mg.) with Bendroflumethiazide (4 mg.) and Potassium Chloride (400 mg.)

SQUIBB 'The Priceless Ingredient' of every product is the honor and integrity of its maker.

The Editor's Soliloquy

Euthanasia — To set you straight.*

From time to time one encounters in the popular media a controversial article decrying the humanitarian intentions of the physician in his effort to prolong the life of a patient during a terminal illness.

No doctor keeps a patient alive without good medical or surgical indication. If a patient survives despite apparently imminent death, it is not because the doctor has administered last-moment stimulants; it is because his initial treatment has succeeded against the odds.

Doctors are not waiting at the grave's edge with an intravenous needle to restore pulse and breath to a moribund mummy. Despite the urgent pleas of distraught relatives who almost invariably implore them to "save no expense" they do, in the terminal illness, only what any good Samaritan would do: they show mercy and compassion.

A patient with an incurable disease who is given a reasonably accurate longevity prognosis may not welcome a premature demise, but when the relatives ask, "Can't something be done, Doctor?" or "Can't you show mercy, Doctor?" are they not virtually suggesting that the doctor act as executioner? Would they themselves be willing to administer the hemlock cocktail? Could they bring themselves to wield the lethal syringe?

No patient is miserable in coma nor does he suffer pain when he writhes in unconsciousness. The delirium of fever or uremia is not distressing. In the valley of the shadow there is no anguished groping for a dubious or chimerical hereafter.

Surely no physician performs an emergency procedure just for the sake of producing a "dreadful ordeal from which there can be no survival, but only prolongation of misery." Weighing the pros and cons the doctor carefully calculates the risk. When he decides to take that risk, it is always in the anticipation and with the prospect of relieving pain, providing comfort, restoring health and extending life. Though there may be moments of "artificial prolongation of physical existence" as the physician discharges his ethical responsibilities to the patient, such moments are exceedingly rare.

Would anyone resent resuscitation measures or an oxygen mask for a drowning child, even though well aware that only a few minutes of oxygen deprivation is sufficient to permanently destroy brain function? Would anyone have enough ice in his veins to say, "Let him die"? Modern methods in medicine have conclusively proven the value of external cardiac massage in many instances of cardiac arrest — with complete restoration. Would anyone suggest that the doctor should have declined to perform it — on the chance that mere physical function might remain and brain function cease?

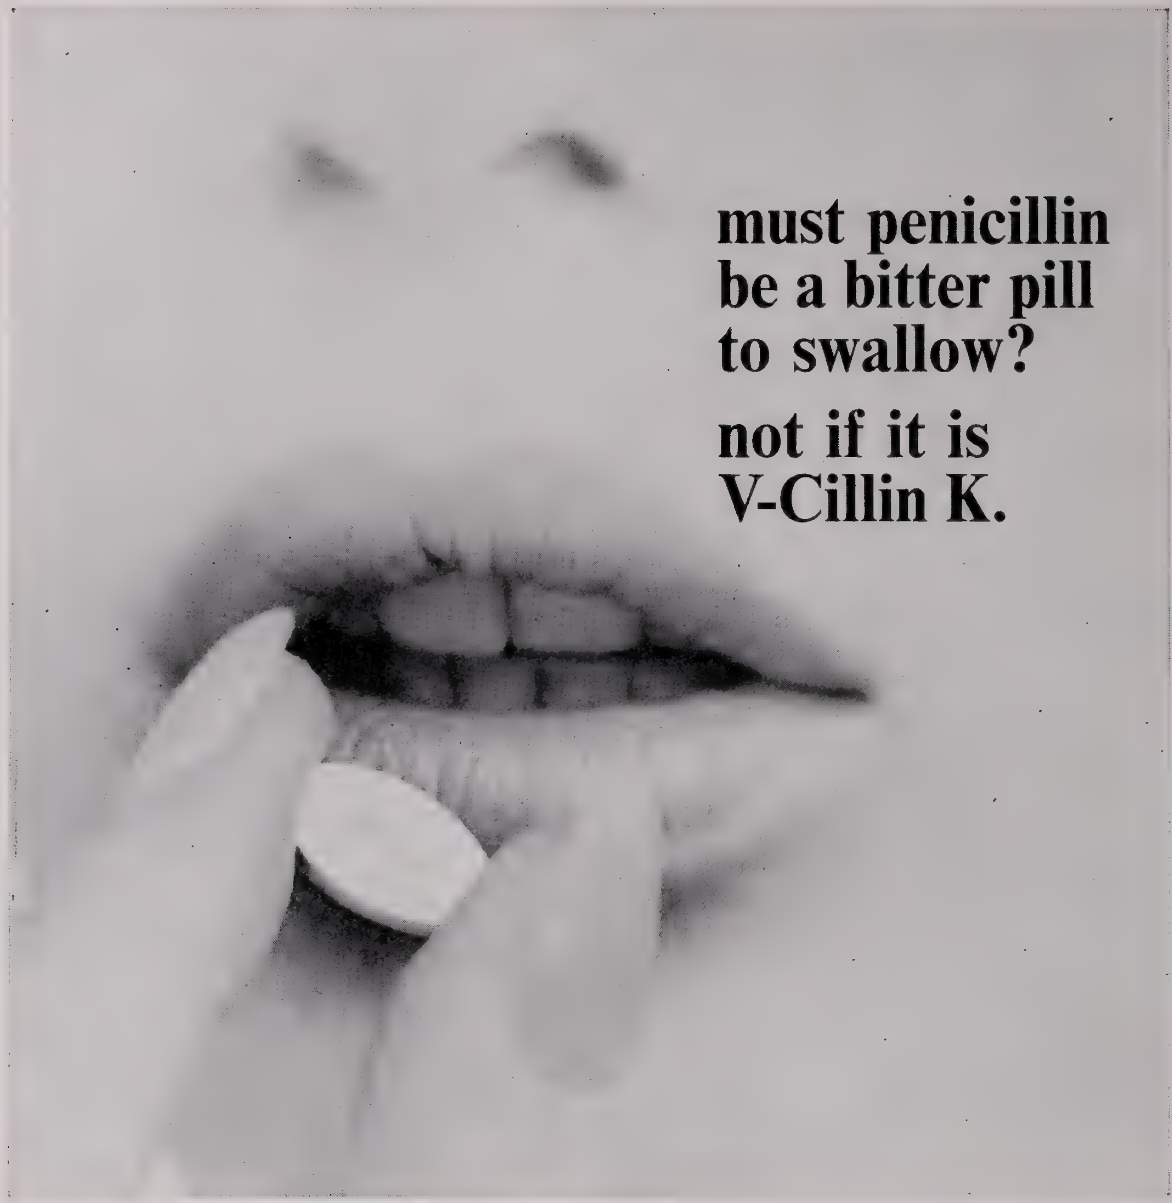
Doubtless most if not all individuals, if they could make the choice, would elect simultaneous extinction of both body and spirit. But who could schedule the optimal moment for that dual passing — and then implement it with dispatch and finesse!

Only when your sands run out is your life finished. Doctors should be charged with neither the responsibility nor the culpability for making it different.

— **Carl O. Rice, M.D.**

---

*In response to Elizabeth Davenport Plant in Vogue, June 1966.



must penicillin be a bitter pill to swallow?
not if it is V-Cillin K.

V-Cillin K now has a unique glossy coating that banishes bitter penicillin taste and makes it easier to swallow. Within six seconds (just long enough for the tablet to get past the taste buds), the coating dissolves and the penicillin is ready for immediate absorption into the bloodstream. The patient still gets all the special benefits of V-Cillin K, including consistent dependability . . . even in the presence of food.

Indications: V-Cillin K is an antibiotic useful in the treatment of infections caused by streptococci, pneumococci, and sensitive strains of staphylococci.

Contraindications and Precautions: Although sensitivity reactions are much less common after oral than after parenteral administration, V-Cillin K should not be administered to patients with a history of allergy to penicillin. As with any antibiotic, observation for overgrowth of nonsusceptible organisms during treatment is important.

Usual Dosage Range: 125 mg. (200,000 units) three times a day to 250 mg. every four hours.

Supplied: Tablets V-Cillin K, 125 or 250 mg.; also, V-Cillin K, Pediatric, 125 mg. per 5-cc. teaspoonful, in 40, 80, and 150-cc.-size packages.

V-Cillin K® **Six-Second Barrier to Bitterness**

Potassium Phenoxymethyl Penicillin

PRESIDENT'S LETTER

(Continued from page 1211.)

of a statement entitled "Application of Criteria for Determination of Reasonable Charges." As this statement was accompanied by a request for comments and reaction, and as both documents incorporated major departures from previous statements issued by Social Security Administration, the Advisory Committee requested and received an appointment for July 1st with Social Security Administration officials. Following this appointment and the subsequent issuance by the American Medical Association of a critique of Social Security Regulation #5 and the statement on charges, further meetings to reconcile the points at issue have been arranged and medicine's objections vigorously presented.

Obviously, continuing efforts by the Medical Advisory Committee and the officers of the American Medical Association will be essential in presenting medicine's viewpoint, indicating medicine's opposition to poorly conceived regulations and defending physician rights. Equally obviously, physician awareness of the competence and dedication with which this program is being followed, the complexity of the task and the need for reconciling various reactions to each successive problem will support the Committee by demonstrating united physician backing for the spokesmen for medicine.

RP Buckley M.D.

R. P. Buckley, M.D.

Oliver Wendel Holmes, M.D.
To the Young Practitioner

You will remember, of course, always to get the weather-gage of your patient. I mean, to place him so that the light falls on his face and not on yours. It is a kind of ocular duel that is about to take place between you; you are going to look through his features into his pulmonary and hepatic and other internal machinery, and he is going to look into yours quite as sharply to see what you think about his probabilities for time or eternity. . . . No matter how hard he stares at your countenance, he should never be able to read his fate in it. It should be cheerful as long as there is hope, and serene in its gravity when nothing is left but resignation. The face of a physician, like that of a diplomatist, should be impenetrable.

In Flux

Probably the most interesting period of medicine has been that of the last few decades. So rapid has been this advance, as new knowledge developed, that the truth of each year was necessarily modified by new evidence, making the truth an ever-changing factor. — Charles Mayo

Pregnancy

The termination of pregnancy is a mysterious affair. Allergy may be the initial spark that initiates the chain reaction of the contraction of the uterus. The importance of the existence of different individual proteins of mother and child for creating allergic interaction between antigen and antibody must be underlined.

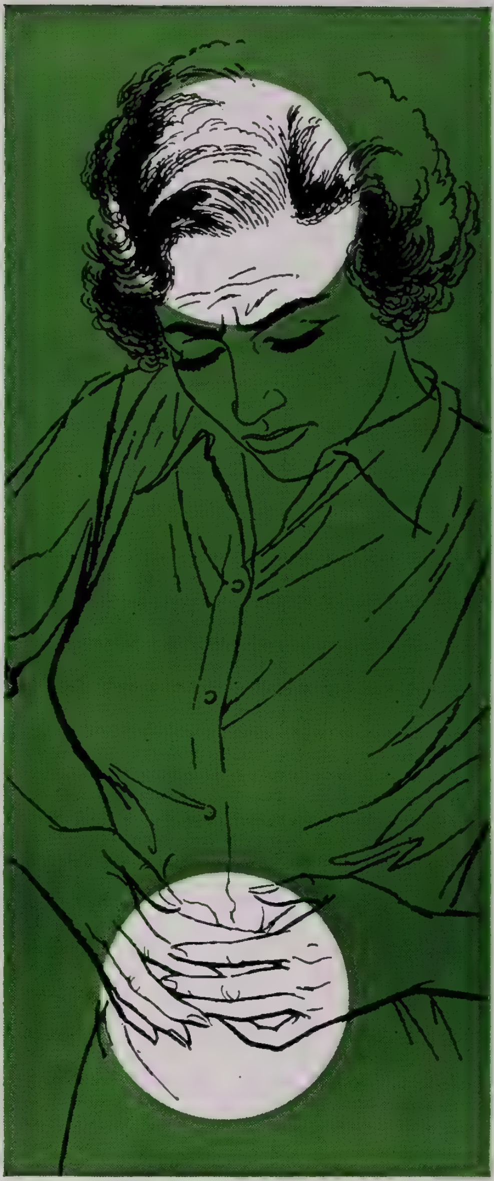
— Bela Shick (1877-)

when agitation accompanies spasm of the 'G. I.' tract.

Butadonna™

BUTABARBITAL SODIUM, 15 MG. (BARBITURIC ACID DERIVATIVE)
WARNING: MAY BE HABIT FORMING
BELLADONNA EXTRACT (TOTAL ALKALOIDS 0.188 MG.), 15 MG

provides gentle, intermediate sedation and relaxes 'G. I.' spasm.



Butadonna quiets the "brain-on-gut" influences by providing the smooth, intermediate sedative, butabarbital sodium, desirable in combination with the proven antispasmodic, belladonna extract. Butabarbital sodium is more rapidly eliminated than phenobarbital, and avoids the latter's cumulative effect.

Indications: Antispasmodic-sedative. Useful in the treatment of peptic ulcer, gastritis, duodenitis, irritable colon syndrome, ulcerative colitis, regional enteritis, and other conditions associated with gastrointestinal spasm. Also may be useful in functional dysmenorrhea.

Usual adult dosage is one tablet 3 or 4 times daily as needed.

Caution: Contraindicated in glaucoma and urinary retention. Reduce dosage or discontinue use in event of blurring of vision, dryness of mouth, tachycardia, or excessive drowsiness. Continued use of butabarbital sodium may be habit forming.

Curbstone Consultation

Ulcerative Colitis

QUESTION: Can you briefly describe the topical steroid application for ulcerative colitis, and could this be done in the doctor's office?

ANSWER: Methods of therapy depended upon anatomical involvement and degree of systemic symptoms. For ulcerative proctitis, with no or few systemic symptoms, suppositories (q.i.d.) were prescribed and the treatment was self-administered. There are several steroid suppositories on the market. For more extensive involvement, retention enemas of a suspension of hydrocortisone acetate (50 mgm.), prednisone (10 mgm.), or methylprednisalone acetate (40-120 mgm.) were prescribed and self-administered at home. For total involvement and for patients with severe symptoms, hydrocortisone sodium succinate (50-100 mgm.) was given as a proctoclysis. All methods of therapy can be used in a doctor's office, although the proctoclysis needs to be given slowly to avoid expelling, and this would tie up office space.

Only hydrocortisone sodium succinate is water-soluble. This preparation is not stable when kept in solution for several days and needs to be used promptly after mixing. The other solutions are suspensions and have to be shaken periodically, if given slowly, to prevent settling out.

Crude Sensitivity Determination

QUESTION: In an individual who smokes excessively and has emphysema, is it necessary to do crude sensitivity determination?

ANSWER: The detrimental effects of the inhalation of the smoke of cigarettes over a period of many years is due to its destructive influence on the parenchymal tissues of the lungs, particularly of the alveoli and smaller bronchioles. Allergy or hypersensitivity to tobacco is not responsible. It is also important to remember that destructive emphysema does occur in patients who have never smoked, resulting from the allergic predisposition and long-standing bronchospasm and edema from perennial asthma, particularly due to allergy to foods.

in chronic illness

B and C vitamins are part of therapy: An imbalance of water-soluble vitamins and chronic illness often go hand in hand. STRESSCAPS capsules, containing therapeutic quantities of vitamins B and C, are formulated to meet the increased metabolic demands of patients with physiologic stress. In chronic illness, as with many stress conditions, STRESSCAPS vitamins are therapy.

Stresscaps®

Stress Formula Vitamins Lederle

FOR PROFESSIONAL RECOMMENDATION ONLY

Each capsule contains:

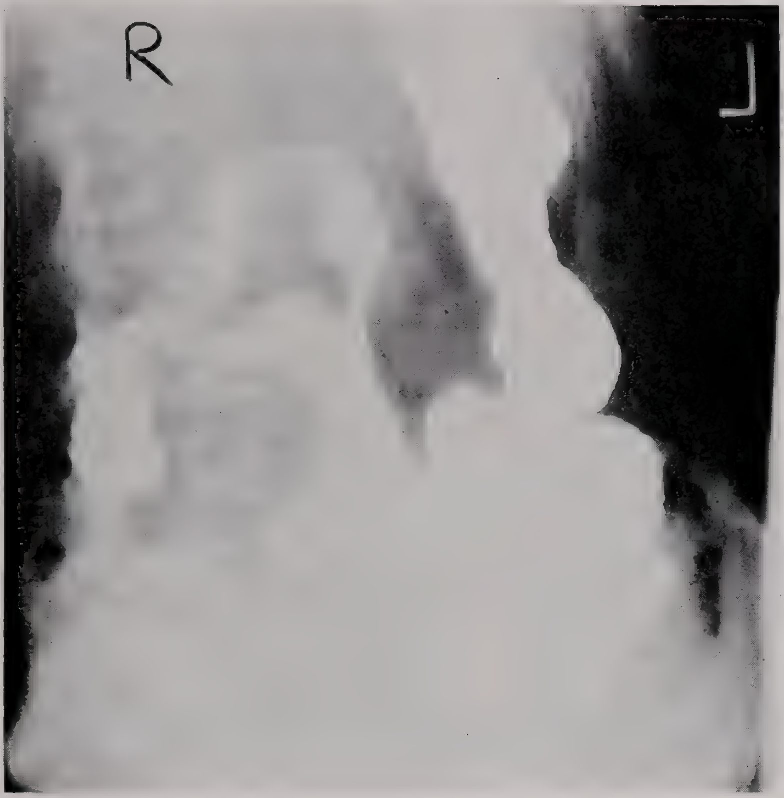
Vitamin B_1 (as Thiamine Mononitrate)	10 mg
Vitamin B_2 (Riboflavin)	10 mg
Vitamin B_6 (Pyridoxine HCl)	2 mg
Vitamin B_{12} Crystalline	4 mcgm
Vitamin C (Ascorbic Acid)	300 mg
Niacinamide	100 mg
Calcium Pantothenate	20 mg

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

LEDERLE LABORATORIES, A Division of American Cyanamid Company, Pearl River, New York

628-6—36

The Viewing Box



THE PATIENT is a 69-year-old female, who was first admitted to the hospital in March 1965, complaining of chronic fatigue. There was a history of ingestion of considerable quantities of aspirin. Laboratory workup at this time disclosed a hemoglobin of 7.6 grams apparently due to iron deficiency. Reticulocyte count was 2.4%. Stool guiac determinations ranged from trace to 2+. The patient had free acid. An upper gastrointestinal series was interpreted as showing a duodenal ulcer. Proctoscopic examination and x-ray examinations of the colon and small bowel were normal. The patient was treated with transfusions and an ulcer regimen with improvement. A follow-up gastrointestinal series revealed partial healing of the ulcer. The patient was maintained on the ulcer regimen and was periodically seen in the office without specific complaints. In March 1966 she was re-admitted to the hospital without subjective complaints, but with vague right upper-quadrant tenderness noted at the time of a routine physical examination. Stool guiacs had remained negative, and the hemoglobin was 12.8 grams. Repeat upper gastrointestinal examination revealed a 5 cm. mass involving the greater curvature aspect of the duodenal bulb (Figure 1). This appeared to be largely extrinsic to the lumen and to be superficially ulcerated.

Differential diagnosis was felt to be primarily that of extramucosal duodenal tumors including leiomyoma or leiomyosarcoma, aberrant pancreas, lipoma, carcinoma, carcinoid, metastasis or pancreatic invasion of the duodenum.

What is your diagnosis? (See next page.)

Diagnosis: Carcinoid of the duodenum.

At surgery a polypoid mass was found involving the greater curvature aspect of the duodenal bulb and protruding through the serosa. There were large lymph nodes encircling the porta hepatis, and nodules in both lobes of the liver. Microscopic examination revealed a carcinoid tumor extending through the entire wall of the duodenum with superficial ulceration and metastases to the liver and lymph nodes. The patient exhibited no stigmata of the carcinoid syndrome, and the 5-hydroxyindolacetic acid determination postoperatively was normal.

Carcinoids are tumors of low-grade malignancy arising from the serotonin-producing argentaffine cells found at the base of the Lieberkuhn glands of the small bowel. They fall into two general categories. Those arising in the appendix have a relatively benign course. They may metastasize to regional lymph nodes but rarely if ever metastasize distantly or give rise to the carcinoid syndrome. Extra-appendiceal carcinoids (about 40%) become progressively more rare as one moves proximally in the gastrointestinal tract. They tend to be more malignant, are often multiple, and in the approximately 15 per cent which metastasize to the liver the carcinoid syndrome is frequently seen.

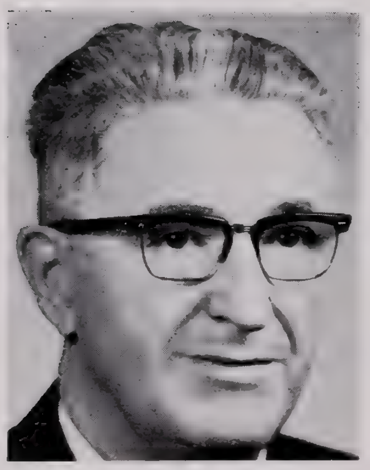
Fifty Years of Honorable Service



Dr. Lawrence J. Leonard

Dr. Leonard was born at Jordan, Minnesota, in 1893 and received his medical degree from Creighton University at Omaha, Nebraska, in 1916. He was licensed in Nebraska in 1916. After serving an internship for two years, first at St. Joseph's Hospital in St. Paul, and then at Fairview Hospital in Minneapolis, he entered the Army Medical Corps and served from 1918 to 1919 in World War I. Following his discharge, he opened a general practice in Minneapolis, with special interest in various fields, including gastrointestinal diseases and allergies. He was also interested in medical-legal problems and received a law degree in 1934 after four years of night study at the Minneapolis College of Law. He has been a member of the staffs of Fairview, St. Andrews and Glenwood Hills Hospitals in Minneapolis. Dr. Leonard has delivered over 8,100 babies, and in his spare time, plays the accordian.

Editor's Note: Because the May issue of MINNESOTA MEDICINE *was off the press at the time Dr. Lawrence J. Leonard of Minneapolis was elected to the 50 Club of the Minnesota State Medical Association, it was impossible to include his autobiography and photograph with the other newly elected 50 Club Members.*

Athletic Injuries

The Prevention and Treatment of Knee Injuries in Athletes[*]

THE TEAM physician or athletic trainer have in many instances an advantage if it can be called such, of actually seeing a knee injury occur in football. Not only do they see the accident happen but are able to observe the immediate reaction of the body to knee trauma from the instant of injury.

A trainer running onto the field in the case of a knee injury observes the injured athlete and how he is reacting to his injury. He may be holding his knee or rolling back and forth, and yet the injured leg is held very still. Because of the equipment that a football player wears we are unable to observe very much except abnormal position of the lower leg on the femur and the position of the knee in flexion or extension. We also observe the athlete himself and his reaction to pain or traumatic shock.

Our first observation of the knee injury is to decide immediately how serious it is and decide whether the athlete can walk off the field by himself, walk off on his good leg with assistance, or be carried off on a stretcher for a more complete diagnosis on the side lines or in the training room.

It is necessary that we *feel* for various signs of disability. We *feel* for any abnormal contour of the leg, the patella, dislocation of the knee joint, fractures of the patella, femur or tibia, or any abnormal bumps or depressions. A brief history of how the injury happened is valuable — not only for pertinent information but also for the opportunity it provides for distracting the athlete's attention from the pain and shock of his injury. Besides getting a brief history we try to calm the athlete, and we never tell him what type of injury he has until he is on the side lines or in the training room. The reason for this is that too many athletes are scared to death that they have a fracture or that their athletic career is at an end. We like to believe that we are treating an injured athlete rather than a knee injury; and we must consider the traumatic shock that accompanies the injury.

Along this same line we prefer that other athletes stay away as we make this preliminary diagnosis lest they make some inappropriate remark or gesture. Their remarks about getting a stretcher or calling an ambulance, or their staring at or pointing to the injury with a distressed or horrified expression or gesture does nothing to relax the tension.

If we feel the injury is severe enough we carry the athlete directly to

---

[*] Presented at 113th Annual Meeting of Minnesota State Medical Association in Minneapolis, May 16, 1966.

Continued

the side lines or training room, telling him we are doing this to be able to make a more thorough examination and that we would rather he would not walk on the leg until we are absolutely sure of the severity of the injury.

When the athlete is in the training room his pants are removed even if it means cutting them off in order not to aggravate the injury; then a complete examination of the knee is made by the attending physician. The severity of the injury is evaluated at this time. If the patient isn't taken to the hospital immediately a pressure wrap is applied to the knee, the entire leg is elevated slightly, and cold packs are applied to the knee until the time it is to be x-rayed. After the x-ray the physician decides upon the best course of treatment, which may be complete bed rest, aspiration, cold packs, pressure, elevation, a cast to immobilize, or even surgery.

Treatment and Rehabilitation of Knee Injury

I have often stated that in order for a boy to be a good athlete he must be able to make his body do what he wants it to do. The athlete with a knee injury is no longer an athlete since he cannot make his body do what he wants it to do because:

1. There may be varying degrees of pain in the leg at rest and/or in motion.
2. There is a lack of full range of motion.
3. There usually is atrophy of the quadriceps and hamstrings and insufficient strength to support the injured knee.
4. The athlete does not have the proper mental attitude because he cannot do what he used to do or has a fear of re-injury.

The goal we strive for is complete or 100% rehabilitation in the shortest possible time without danger or risk of a more serious injury or a residual injury that may handicap the athlete later in life. This goal is the responsibility of the physician, the athlete, the coach, and the trainer, and they must all understand the situation and work together.

The course of treatment of the knee injury is decided by the physician, and the athlete reports to the training room for treatments. Because he may come with only an ace bandage on his knee or a half cast or even on crutches depending upon the condition of the knee, one or more of the following treatments may be used.

1. Heat — hot packs or whirlpool bath usually not until 24 to 36 hours after the injury. This type of treatment should last 20 or 30 minutes.
2. Stretching of the hamstring muscles. After preliminary heating these muscles may have to be stretched; otherwise the athlete may walk or hold his knee in the most comfortable position of 10°–20° of flexion.
3. Therapeutic exercises. These may be active, passive, assistive, progressive resistant or isometric, depending upon the need. These exercises are to restore mobility or range of motion of the knee and build strength or prevent atrophy if it hasn't already started. Straight leg raising from a supine position or exercises from a sitting position with the lower leg hanging over the edge of the table at a right angle are effective. If there is evidence of chondromalacia of the patella we prefer to start exercising the knee at 45° instead of 90° to prevent irritating the posterior aspect of the patella. To gain range of motion we use active and passive knee extension and return to starting position without

weights. To build strength and endurance we can add resistance either by a weighted boot attached to the foot or by a pulley arrangement attached to the tibia.

If surgery is performed, rehabilitation is necessary to increase the range of motion and to restore strength and endurance equal to that of the uninjured leg. The surgeon recommends postoperative exercises. During the patient's four or five day stay in the hospital he usually does straight leg raising exercises that he has been taught how to do before surgery. These are usually done for about five minutes for each hour of the day that he is awake. The methods for building strength endurance in a weakened muscle are an exact science because of the splendid work and experiments of De Lorme, Rose, Beasley, Hellebrandt and many more physicians, physiologists and physical educators.

It has been determined that the quadriceps muscle can gain or lift from five to seven pounds more weight each week by progressive resistance exercises (P.R.E.). This is done either by adding a small increment each day of 1¼ pounds or by adding the total additional weight at the beginning of each week. This should be done by a doctor's written prescription and by a physical therapist for best results.

Many athletes, especially at the high school level come to the training room each year for help with their knee problems, and the one I see most often is the athlete that has injured his knee, usually a medial collateral ligament sprain, and then rested for two or three weeks and returned to sports after the pain has gone and he or the coach thinks he is ready to play but much to his surprise the knee is re-injured.

These athletes show a definite atrophy and flabbiness of the quadriceps, and I try to impress upon them that the strength of the knee joint is determined by the strength of the quadriceps and hamstrings that are so important in its function. On knee extension they should be able to lift 75 to 100 pounds before returning to sports. Some can lift 40 or 50 pounds and feel this is enough for the quads. The hamstrings being about 60% of the strength of the quadriceps, their strength should be in the proper proportion.

In a brief summary of the vast subject of knee injury in athletes, I would like to suggest the following points:

1. An exact and complete diagnosis of the knee injury by a physician as soon as possible after the injury.
2. Written instructions or diagrams of exercises to be done by the athlete to prevent atrophy and to increase strength and endurance.
3. Always a final check of the knee by a physician before the athlete is allowed to return to sports competition. He must not be returned until he has met the following qualifications: (a.) freedom from pain. (b.) complete range of motion — active and passively, (c.) no atrophy or at least adequate strength to support the injured knee, (d.) proper mental attitude.

If he has the first three, he usually has the proper mental attitude.

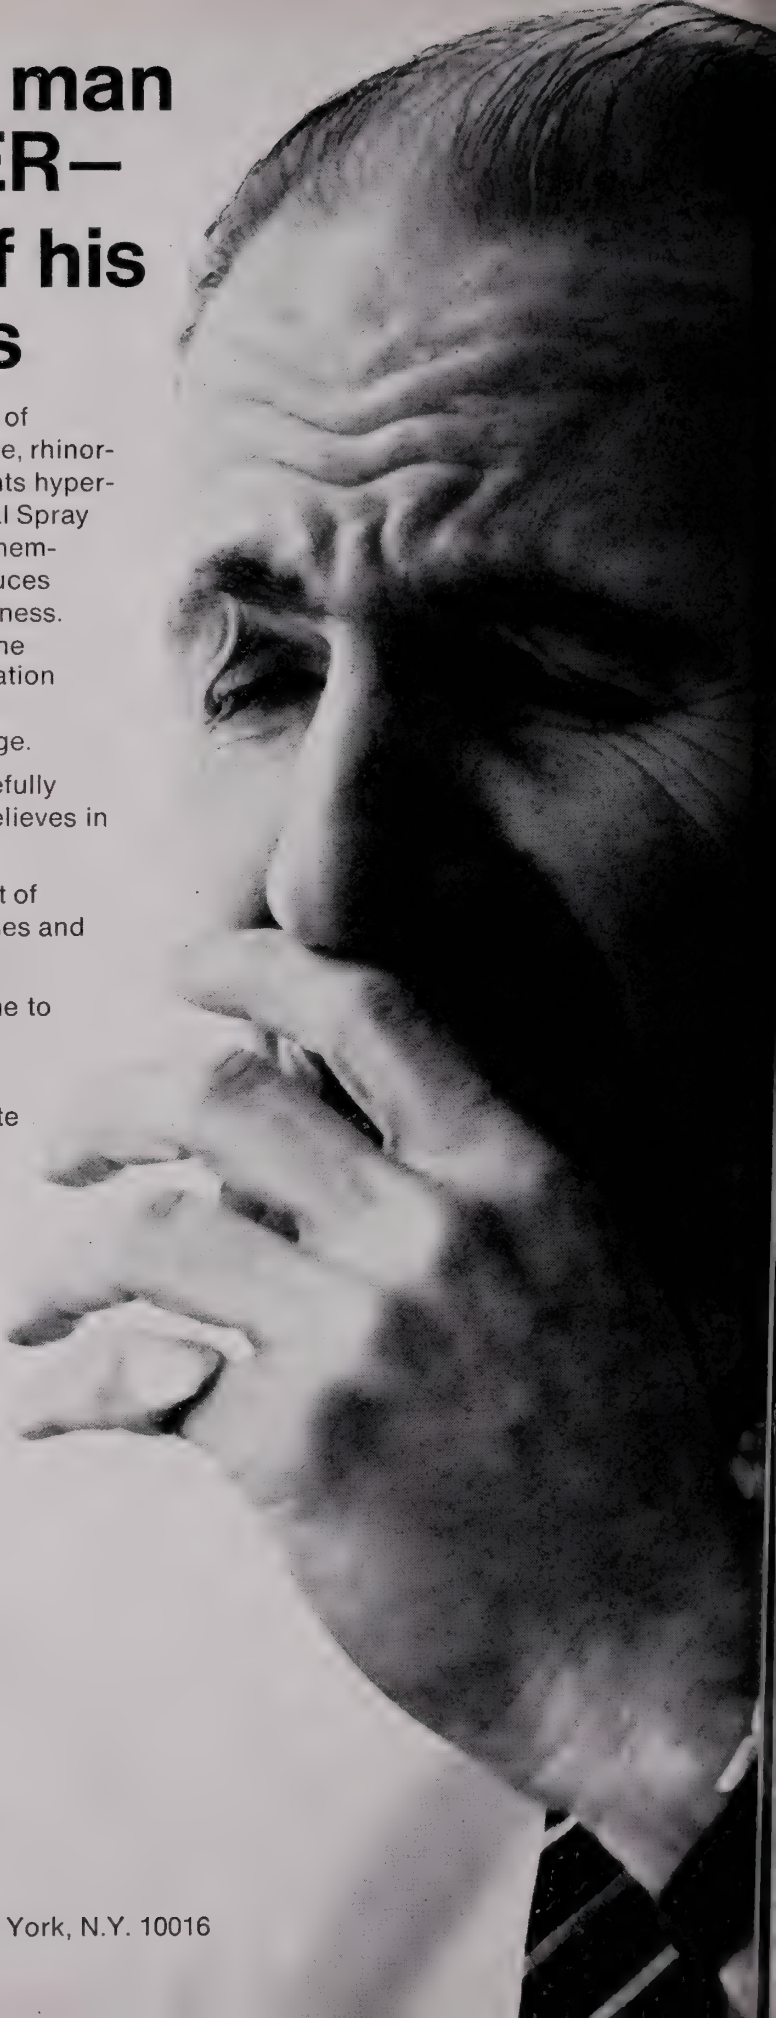
Work is the truly indispensable vitamin. — Dorothy Canfield Fisher

Once merely a man with HAY FEVER—now a victim of his own antibodies



Whatever term describes him in this new era of immunology, the symptoms of congested nose, rhinorrhea and sneezing haven't changed in patients hypersensitive to pollens and molds. But NTZ® Nasal Spray relieves the symptoms. It decongests nasal membranes on contact, relieves itching and reduces excessive rhinorrhea without unpleasant dryness. The first spray of well-tolerated NTZ shrinks the turbinates, helps restore normal nasal ventilation and breathing. After a few minutes, a second spray enhances sinus ventilation and drainage.

More than a simple vasoconstrictor, the carefully balanced formula of effective components relieves in three ways with:

- **N**eo-Synephrine® HCl 0.5%, a decongestant of unexcelled efficacy to shrink nasal membranes and allow more comfortable breathing.
- **T**henfadil® HCl 0.1%, a topical antihistamine to help relieve itching and rhinorrhea.
- **Z**ephiran® Cl 1:5000, an excellent wetting agent and antiseptic preservative to promote the rapid spread of components to less accessible nasal areas.

Supplied in convenient pocket-size plastic spray bottle of 20 ml. Also available as a solution of 30 ml. (1 fl. oz.) with dropper, and 473 ml. (1 pint).

Prescribe

NTZ® Nasal Spray

Winthrop Winthrop Laboratories, New York, N.Y. 10016

Neurological Conference

Associated Problems with Parkinsonism[*]

Doctor Stanley Norman[**]

The patient is a 71-year-old white female who was seen in New Medicine Clinic for the first time on June 23, 1964, with the main complaint of a nervous stomach. Her difficulties began in early 1962, approximately one-half year after the death of her husband. She stated that she was constantly jittery, nauseated and tired. She did not enjoy being with people and had lost interest in doing anything. She did not have any plans for the future because she felt so miserable. She has had a 56-lb. weight loss during the past 2½ years. About two years ago she developed a dragging of the left foot and felt that her strength was diminishing. She then also noticed difficulty using her hands when trying to knit or sew. These symptoms have continued to the present time.

Her past medical history and review of systems were unremarkable. Her husband died 2½ years ago from aplastic anemia. The patient had spent much time caring for her husband at home and stated that she took his death very hard. Several married daughters are living nearby and visit her frequently.

Physical Findings

The physical examination revealed an asthenic, nervous, elderly lady who paced the floor during the interview. She had a mask-like facies which showed very little expression. Her blood pressure was 155/90 mm.Hg. and her pulse 92/minute and regular. There was a questionable nodule in the left lobe of the thyroid. On neurological examination the striking finding was a distinct rigidity in both upper and lower extremities. A very slight tremor of the extremities produced minimal evidence of cogwheeling on passive movement of the arms and legs. Her gait was characterized by short shuffling steps and there was a tendency to drag her left

---

[*] Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatrics conferences are held every Wednesday from 1:00 to 3:00 p.m. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Charles Branthaver and Dr. Edward Defoe in Pediatrics, and Dr. Robert Soll, in Adult Neurology.

Held on May 20, 1965.

[**] Student Doctor, University of Minnesota Hospitals.

Continued

foot. Associated movements of her arms while walking were virtually absent. The deep tendon reflexes were essentially equal and no Babinski sign or clonus was apparent. Cranial nerve examination revealed an anisocoria,* the left pupil being somewhat larger than the right.

The patient's laboratory examinations all proved to be normal. These included the routine blood work, urinalysis, two-hour post-prandial blood sugar and several tests for hyperthyroidism.

Treatment and Response

Initially she had been treated with Elavil and Compazine. Eventually we added anti-Parkinson medications which included Cogentin and Artane. On this regimen she has shown some improvement, primarily in having less rigidity. Her face seems to have become more expressive, although she still has few associated movements of her arms while walking. Her depression has fluctuated throughout the course of treatment, depending to some extent on the dosage of Elavil, and she has been hostile and resistant to treatment at times. Her weight has fluctuated between 96 and 108 pounds; however, after increasing the Elavil, her weight increased to 111 pounds. Medication has not relieved her persistent nausea and her mood is still somewhat that of a depressed individual.

The Evaluation

Dr. Soll

Has the patient had a history of influenza?

Dr. Norman

No, she hasn't.

Dr. Soll

This would suggest that her parkinsonism was more arteriosclerotic than encephalitic in origin. Her age at onset of symptoms would also agree with this.

Dr. Ben Fuller**

The dragging of her left foot has been present longer than two years. Her main problem, as far as I was concerned, was not the parkinsonism, however, so much as her depression and weight loss.

Dr. Richard Magraw†

I believe she may have had two light strokes while we have been seeing her. These were in the nature of a very transient hemiparesis. The symptoms she gave seemed quite definite, although she was not confined to bed. Her most recent instance of this was three months ago if I remember correctly. Initially Dr. Fuller and I were very concerned about her weight loss. Also she has had a persistent tachycardia which remains unexplained. She presented a rather opaque and contradictory history as well as being quite opposed to any change in her therapy. Throughout our care she has presented a fog of somatic symptoms which have been quite elusive and difficult to pin down.

---

*See Test Your Word Score Page 1267.

**Referring physician.

†Director, Comprehensive Clinic, University of Minnesota Hospitals.

Dr. Soll

Were you able to determine a definite date of onset of the dragging of her left foot?

Dr. Fuller

No, the patient didn't know that she was dragging her foot. Her children were the first to notice it but they didn't know when it had begun.

Dr. Soll

Her reflexes and coordination at the present time would not be consistent with any permanent residual damage characteristic of a completed stroke. She may have had a temporary cerebral ischemia; however, the lack of a definite onset and the long duration of the dragging of her left foot would not favor a transient ischemia.

Dr. John Brantner*

I wasn't able to obtain any testing immediately prior to this conference. I did talk with her and she showed this same subtle resistance. I thought that I saw the characteristic kind of prolonged grief and bereavement that one does see in some elderly people. She spoke vividly of her husband's death which was followed within a period of one year by the death of three or four of her closest friends. This showed a clear indication of depression.

Two multiphasics, one of which was done a year ago, did not show any signs of depression; however, another taken in December 1964, clearly revealed depression and anxiety. She described herself as being reasonably devout, at one time very active in church; but now she doesn't attend church anymore. I have the feeling that there is no real positive pleasure or delight in her life. Besides being bereaved over the deaths of the people she has known and loved, she is lonely, recognizes a decline in her powers, and probably fears that the daughter with whom she is living may be considering moving. She didn't talk to me about this last possibility, but I learned about it tangentially. Her daughter has received job offers from another state and has been considering them. This may be a significant factor in the patient's depression.

Dr. Soll

Depression and loss of weight are quite common in Parkinson's disease. Much of the weight loss in parkinsonism may be due to a patient's difficulty in feeding himself or swallowing. In the advanced disease many Parkinson patients are thin.

Dr. Fuller

The death of her husband was not as insurmountable for her as the death of her son-in-law. She became quite agitated at the time of his death and that is when she developed the weight loss. He was a young man, not ill at all, and fell over dead in church. After he died she never spoke of his death, and I don't know if she does yet.

---

*Clinical Psychologist, University of Minnesota Hospitals.

Continued

Dr. Magraw

I would like to ascertain the actual relationship of her husband's death to her illness. If it is a matter of unresolved grief, as Dr. Brantner has pointed out, we should be able to deal with it in the ordinary way by talking with the patient — even at this point; however, she is not the usual patient in that she is a very difficult person to talk to.

Dr. Fuller

You explored the question of thyrotoxicosis, didn't you?

Dr. Magraw

Yes, very carefully, because I felt she might have an occult thyrotoxicosis manifested by tachycardia.

The protein bound iodine was 5.9 micrograms %, the radioactive iodine uptake was 30.3% in 24 hours, and the total creatinine and creatine was 0.84 grams per 24 hours.

One of the aspects of her case that prompted me to present her to this conference was the question of whether we should further investigate the possibility of cerebral vascular insufficiency by angiography. Also I would raise the possibility of using electroshock to treat her depression. She has responded to Elavil, but she is far from free of depression.

Dr. Soll

I could not detect any bruits in her carotid arteries. Significant artereosclerosis could be responsible for both the parkinsonism and the transient episodes of right hemiparesis. The absence of a carotid bruit either would suggest no involvement of the carotid circulation at all or could signify a complete occlusion of the carotid artery. But even if one were found, the age and general condition of this patient would argue against surgery. Anticoagulation would be another possible approach for treatment of an insufficiency; but this too has some serious drawbacks in view of her age, depression, and resistance to treatment.

Dr. Norman

Would vasodilators be of any benefit?

Dr. Soll

Vasodilators do not usually affect cerebral circulation significantly. Also, they may cause dilatation of other vessels in the body and thus detract from the cerebral circulation.

Dr. Fuller

What is the possibility of giving her electroshock therapy? It might be worth trying if her depression fails to respond to more conservative therapy. Are there contraindications to its use?

Dr. Magraw

Primarily the general fragility of a patient at this age.

Miss Helen Kretchmer*

I saw the patient after she had been interviewed in psychology. At that time she was already feeling weary and complained much about her nausea. I was impressed by the fact that she was good-looking and nicely dressed.

The patient and her daughter live in a pleasant neighborhood in a home that has belonged to the family for 25 years. As of now she has no difficulty in climbing stairs, but there are many steps both inside and outside the house. The family consists of four daughters, ages 30 to 45 years. The patient's three married daughters live in the same neighborhood and visit her frequently. There are several grandchildren, ages eight to 22. Although the grandchildren are busy with their own affairs and do not visit her often, she would like to see more of them.

The patient completed high school and business college, after which she worked as a secretary until her marriage at age 21. She worked long enough after 1935 to enable her to obtain Social Security coverage, which now provides her with a retirement income of $97.50 a month. The patient stated that she was still able to do housework although her hands are weak. She and her daughter maintain the house together.

Many of her interests are curtailed now because of nausea and discomfort. She had sung soprano in the church choir for many years but gave this up because of her age. She also played the piano, although her hands are not strong enough for this now. It appears that she would have ample opportunity for an adequate social life if she felt able to enter into activities. I thought a combination of factors were involved with this patient as with many older persons. She has lost her husband and her children are grown. Also she has physical and probably mental disabilities that limit her mobility, independence, and satisfactions in life. The physically-limiting problems serve to make her problem more of a reaction-depression type of situation. Like Dr. Magraw, I also felt that the family shored her up sufficiently so that she appeared more adequate than she would actually would be if left to her own devices.

The Management

Dr. Magraw

One of the complicating factors at the beginning of my contact with this patient was that it was not initially possible for me to make a diagnosis of depression. As you recall she was taking Elavil but complained that the pills made her nauseated. On the other hand, if she didn't take the pills she also became nauseated. In addition, she was also taking syrup of compazine, a medication which raised the question of a possibility of drug-induced rigidity simulating parkinsonism. But after we gradually weaned her from both medications against her will, it became clear that she had quite severe parkinsonism manifested more by rigidity than tremor. Her depression and agitation also became much more apparent after she was off Elavil. I promptly restarted these medications, and again there was a reasonable improvement. During all this time we were giving her liberal psychological support.

Initially she would not let her daughter leave the examination room;

Continued

she would not even keep an appointment by herself. I really feel that she has made many unnecessary demands on her family. One of the things I would like to determine is whether there are any other means by which we can shore this woman up other than having her lean so heavily on this one particular daughter.

Miss Kretchmer

Another companion in the home who could be with the patient during the day while her daughter is gone might be helpful. This would not necessarily have to be a homemaker but someone who could come into the home for perhaps a few hours during the day, such as for part of the morning and over the lunch hour.

Dr. Magraw

We might try to work out a rotation with the three other daughters. Also, there is a girl living next door who is a trained occupational therapist. Though the patient has limitations with what she can do with her hands, this might be a possibility.

Dr. Soll

From the neurological point of view, it is very hard to be optimistic about this type of patient because Parkinson's disease usually has a steady downhill course. Although neurosurgical procedures have helped some patients with severe tremor, little benefit is obtained for the rigidity by such an approach. Surgery may alleviate the tremor temporarily, but it often will recur within months or a year or two. I think this patient is very typical of many Parkinson patients in that she is impatient and demanding. These patients hate crowds and are dependent on their families for their temperamental needs. They don't want to be bothered or irritated, yet they desire to be waited on hand and foot. It is important to discuss all these factors with the patient's family so that they will be able to understand the situation thoroughly. The family must also realize that there will be more problems as time goes on.

Miss Kretchmer

Do you think this patient will eventually require nursing home care?

Dr. Soll

I think that she very definitely may need it. Her family is able to care for her fairly well now because she can still perform much of her own self care; nevertheless, most families reach a point where they can no longer meet the demands that such a patient may place upon them. Parkinson patients eventually need almost constant care. They may become bed-ridden and develop decubitis ulcers particularly over the knees, sacrum and elbows. Very likely they will require someone to feed and bathe them. Also hot weather during the summer will present a discomforting situation for these patients and aggravate the existing problems. At the present time the patient's anti-Parkinson medication is almost maximal, and I doubt that it should be increased again, since the probability of further improvement with more medication is poor.

Dr. Fuller

One of the things that has raised the patient's spirit frequently in the past was to go swimming at the YWCA with her daughter twice a week. She thought this was great. Outside activities of this nature, if they were still possible, would increase her interests.

Dr. Brantner

Swimming is no longer associated with youth; there are programs in Saint Paul that are encouraging teaching older people, like women in their 80s, to swim. Just the other day a woman 85 years of age had just learned to swim for the first time and she was enjoying it. The elderly and rather fragile are getting a great deal of benefit from this exercise because it facilitates the release of their body from the full effect of gravity. It's pretty amazing!

The Conclusions

The following conclusions can be drawn from this conference:

1. The patient should be encouraged to participate more in activities outside her home. Swimming is particularly recommended, as well as increased social activities.
2. The possibility of additional part-time help to assist in caring for the patient should be explored. This would relieve some of the burden from the family and add a further sphere of interest for the patient.
3. The question of nursing-home care should be discussed with the family in order to prepare them for this eventuality.
4. Continued conservative care of the patient's depression can be continued for several months until it is determined whether the above steps have been beneficial. If the depression does not improve, further consideration may then be given to the use of electroshock therapy.
5. Additional increases of anti-Parkinson medication probably would provide no additional improvement in the patient's Parkinson symptoms.
6. Anticoagulation therapy or further investigation of her cerebrovascular status is not recommended at this time because of lack of substantial evidence for transient episodes of ischemia.

Robert Soll, M.D.
University of Minnesota Hospitals

Participating in the conference were Dr. John Brantner, Clinical Psychologist; Miss Helen Kretchmer, Supervisor and Assistant Professor of Social Service; Student Doctor Stanley Norman; Dr. Richard Magraw, Director Comprehensive Clinic; Dr. Ben Fuller, Referring Physician and Dr. Robert Soll, Neurologist.

Lettuce

So harmless is lettuce that it may safely be eaten raw in fevers; it allays heat, bridles choler, extinguishes thirst, excites appetite, kindly nourishes, and, above all, represses vapours, conciliates and mitigates pain, besides the effect it has upon the morals — temperance and chastity. — John Evelyn

If you have the right to complain when there is nothing to complain about, you are living in a democracy. — Banking

Democracy is built by those who live to give and destroyed by those who live to get. — Swanson Newsette

Better Service, Doctor?

As far as Blue Shield is concerned, Doctor, the second most valuable thing about you is your signature . . .

. . . your service is the first.

Don't merely give your secretary carte blanche to sign claims on your behalf. Be sure to add your initials if you have delegated authority to make claims on your behalf. Accuracy is important to be sure Blue Shield pays the right fee. Only you can be sure it's accurate.

A business manager may be authorized to sign all claims submitted by a group or clinic.

Help us help you. Your John Henry is our OK to pay!

Medical Seminar

Prenatal Care and Delivery of a Diabetic Patient

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

THE DIABETIC female enjoys virtually the same statistically favorable outlook as does the nondiabetic female with regard to fertility, maternal mortality, and the incidence of spontaneous abortion. When one recalls that Eastman and Hellman[1] consider untreated diabetes and pregnancy to be basically incompatible, the importance of management of the diabetic, particularly that of the pregnant diabetic, is immediately apparent.

Kyle,[2] in 1963, compiled comparative statistics that revealed a decrease in fetal loss from a mean of 40% in series collected between 1930 and 1940, to a mean of 15% in series collected between 1950 and 1960. While fraught with the pitfalls inherent in comparative statistics, this compilation of perinatal mortality suggests marked improvement in the management of the pregnant diabetic during the past three decades. The factors held responsible by various authors for this improvement will be outlined. Management of those patients whose diabetes is of such severity as to require the use of insulin for control will be discussed.

Although the importance of many factors of management remains highly controversial, it is generally agreed that other factors have contributed substantially to improvement in both fetal and maternal welfare.

Common to virtually all programs of management of the frankly diabetic patient are (1) meticulous prenatal care, (2) delivery prior to the end of the thirty-seventh week of gestation, and (3) treatment of the newborn as premature, regardless of weight. Only the first two of these factors are within the scope of this paper.

The Team Approach

The "team approach" to management has been stressed by many authors. The reason for this emphasis is apparent when one reviews the relationship of the type of medical supervision to the perinatal death rate. As reported by Gellis and Hsia[3] and by Hagbard,[4] the perinatal mortality rate is consistently lower when the pregnant diabetic is managed by a team of physicians rather than by an individual physician. Furthermore, as a general rule, the more experienced the team, the lower the perinatal mortality rate.

The "team" is comprised of obstetrician and internist, who are joined at the appropriate times by anesthesiologist and pediatrician. Pedowitz and Shlevin[5] stressed the importance of the patient herself as a vital member of the management team.

Initial Evaluation

Ideally, every diabetic in the child-bearing age group, should, as part of her diabetic training, be made aware of the need to keep accurate menstrual records and to seek prenatal care as early as possible in the event of pregnancy. It is the responsibility of the obstetrician to convey these instructions to diabetic patients and their families when the opportunity presents itself. Furthermore, the need for such instructions should be repeatedly emphasized by the obstetrician to his medical colleagues, namely, internists, pediatricians, and general practitioners, who are most likely to deal with young diabetics.

For the diabetic, it is especially important to seek prenatal care early in pregnancy be-

Continued

cause, according to Kyle,[2] "the longer the period of supervision the greater the likelihood of a successful outcome."

At the time of the first prenatal visit, the obstetrician should, in the course of the usual history-taking and physical examination, pay particular attention to factors bearing on the estimated date of confinement. (Estimated date of confinement as used herein will mean "full term.") Accurate estimation of this date is essential because of the anticipated termination of pregnancy prior to term. The obstetrician must, throughout pregnancy, keep this date in mind and employ all necessary means to ensure accuracy of his estimate. Menstrual irregularities, common in diabetics, may make the initial estimate difficult. Therefore, a meticulous history must be taken and recorded. The patient should be given a calendar to view while trying to recall dates. Dates of intercourse, especially when relatively infrequent, may be helpful. Questions regarding factors that influence frequency and timing of intercourse such as husband's occupation, trips, illness in the family, presence of house guests, anniversaries, social events, and holidays may aid in determining the date of conception. In instances in which the date of conception can be determined, the estimated date of confinement should be calculated to occur 267 days later.

When dealing with patients who have prolonged but regular menstrual intervals, the obstetrician should recall that the preovulatory phase of the cycle is most likely to account for the prolongation. Therefore, the date of conception should be estimated as having occurred approximately 14 days prior to the expected date of menstruation, and the estimated date of confinement should be altered accordingly.

Severity of Disease

A classification of the severity of the patient's diabetes should be made because of subtle differences in management that are dependent on severity of the disease. In addition, classification will aid in the subsequent statistical comparison of the results of this management. Although numerous classifications of diabetes have been proposed, White's[6] classification has been employed most widely.

White's Classification

White's classification is based on (1) age at onset, (2) duration of diabetes, and (3) extent of any vascular and renal complications. There are six classes: *class A*, abnormal glucose tolerance test only, no insulin required, and no fasting hyperglycemia; *class B*, onset after age 20 years, duration of 0 to 9 years, and no vascular disease; *class C*, onset between age 10 and 19 years, duration of 10 to 19 years, and no vascular disease; *class D*, onset prior to age 10 years, duration of 20 years or more, and calcification in legs or retinopathy or both; *class E*, calcification of pelvic vessels; and *class F*, nephropathy.

Associated Complications

The extent of vascular complications must be determined. Retinoscopy must be performed and a careful search made for abnormalities in *renal* and *cardiac* status. Necessary laboratory studies include blood glucose value, blood urea concentration, complete blood count, chest roentgenogram, serologic test, blood type and Rh factor, urinalysis, and electrocardiogram. Kyle[2] recommends that phenolsulfonphthalein excretion be determined and notes that renal biopsy is helpful in differentiating types of renal disease. Because of the prognostic significance of calcification of pelvic, abdominal, and lower-extremity vasculature, roentgenograms of these regions are indicated in many diabetics; but such roentgenograms should not be performed during the first trimester.

Some physicians doubt that rigid diabetic control significantly alters the appearance or severity of vascular changes in diabetics. For this reason, they do not attempt rigid control based on blood-sugar levels but prefer instead "to treat the patient rather than the blood sugar." Certain laxity in metabolic control may (or may not) be acceptable in the management of the nonpregnant diabetic, but it is totally unacceptable in modern management of the pregnant diabetic.

The fetal loss associated with *acidosis or coma* or both in pregnancy is inordinately high. Kyle,[2] in a collected series, reported fetal loss of 30.1% associated with acidosis (1,039 cases) and a fetal loss of 64.5% after maternal coma (1,538 cases).

Hospitalization in Early Pregnancy

Many authors, including Eastman and Hellman,[1] Carrington,[7] and Pedowitz and Shlevin,[5] recommend hospitalization for initial studies of the pregnant diabetic. The controlled activity and diet and the ease of obtaining frequent blood- and urinary-glucose determinations enable the internist to evaluate the metabolic pattern of the individual and to make alterations in the insulin dosage schedule to fit the patient's needs. The time spent during hospitalization may also be utilized to further educate the patient in diabetic dietetics. Because nausea and vomiting may be or may soon become a problem, she should become familiar with the liquid equivalent of her prescribed caloric intake. It may also be necessary for her to review procedures for regular home-testing of urine for glucose and ketones. The final advantage of hospitalization is that it aids in impressing upon the patient the need for rigid control of her diabetes, stresses her active participation in the control program, and serves to improve her rapport with the other members of the management team.

Diet

In general, optimal gain of weight during pregnancy is the same for the diabetic as for the nondiabetic. Kyle[2] stated that, although the obese patient requires fewer calories, she should not be restricted to less than *1,200 to 1,400 calories per day* and suggested that caloric intake be based on ideal weight plus an additional 100 to 200 calories daily to meet the requirements of pregnancy.

Kyle,[2] Carrington,[7] and Pedowitz and Shlevin[5] agree that the diet should provide *1.5 to 2.0 gm. protein/kg/day.*

There is also general agreement that *50 to 75 gm. of fat* and *150 to 250 gm. of carbohydrate* are satisfactory ranges for these substances in the average diabetic diet. Disagreement exists as to whether adjustments in the dietary prescription are made best by varying the amount of carbohydrate or of fat in order to obtain the desired total calories.

Daily sodium intake should be restricted to 1.0 to 2.0 gm. throughout pregnancy.

Supplementary vitamins and iron should be prescribed as they are for the pregnant nondiabetic.

Visits

Carrington[7] recommends weekly visits to both prenatal and diabetic clinics. Kyle[2] suggests biweekly visits to the obstetrician and internist during the first half of pregnancy and weekly visits to each thereafter in order to maintain rigid diabetic control.

Should any doubt exist regarding the expected date of confinement, it would seem wise for the patient to begin weekly visits to the obstetrician by the sixteenth week if she has not done so before. Admittedly, quickening and the date of detection of the fetal heart beat are not precise measurements of fetal age. Nonetheless, these events should be determined as accurately as possible because the date of their appearance may, in combination with other observations, aid in making necessary alterations in the expected date of confinement. For the same reason, fundus height and fetal size must be carefully noted, and the obstetrician must always bear in mind the errors to which such measurements are subject. It must be remembered that the incidences of hydramnios and macrosomia are increased in diabetics but that infants born of mothers having cardiovascular-renal disease may be smaller than normal for gestational age.

Insulin

At the present time, insulin is the drug of group is more a result of the excellent diabetic, obstetric, and pediatric care provided than of the hormonal therapy employed.

Predelivery Hospitalization

Kyle[2] stated that prompt hospitalization is mandatory for such complications as mild toxemia, hydramnios, urinary-tract infection, and inadequate diabetic control. He cited evidence of decreases in uterine circulation, renal blood flow, and urinary estriol associated with activity and, therefore, believes that bed rest may result in in-

Continued

choice for the control of the deranged metabolism in the pregnant diabetic. Although considered teratogenic by some authors, this agent has been used in millions of pregnancies and has resulted in an extremely low teratogenic index. In addition, no proved preferable alternative is available at the present time.

If and when the possibilities of teratogenesis, fetal beta-cell hypertrophy, and derangements of maternal hepatic function have been eliminated, the sulfonylureas may become useful in the control of selected cases of diabetes in pregnancy.

In most instances, a dosage form of insulin having an intermediate duration of action, such as neutral protein Hagedorn (NPH), is employed as the basic replacement therapy. Its use is supplemented by the addition of regular insulin as needed to ensure rigid control. The flexibility provided by regular insulin is especially necessary early and late in pregnancy. The presence of nausea and vomiting may require use of regular insulin as the sole dosage form in early pregnancy. Flexibility in control is again essential just prior to parturition and also during the first 72 hours after delivery.

Increase Use of Insulin

As a general rule, the insulin requirement of the pregnant diabetic increases as pregnancy progresses. There is usually little or no rise during the first trimester, a gradual rise during the second trimester, and a rather abrupt rise early in the third trimester (28 to 30 weeks). From weeks 30 to 37 the insulin requirement tends to increase moderately. A gradual decrease in insulin requirement may occur for two to three weeks prior to spontaneous labor and delivery at term, but this phenomenon is rarely observed today because most pregnancies involving diabetics are terminated from two to five weeks prior to term.

It is essential to realize that the above pattern of increased insulin requirements applies generally and that many exceptions occur. Jones[8] and Pedersen[9] reported that only about two thirds of their pregnant diabetics required increased insulin dosage, whereas in one fourth the requirement was unchanged, and in one tenth the requirement actually decreased during pregnancy. It is, therefore, evident that the changes in insulin dosage during pregnancy cannot be predicted for the individual patient and that frequent blood-sugar determinations are essential for maintenance of excellent control.

Decrease Insulin Requirement

Two additional observations deserve consideration: (1) A decrease in insulin requirement that occurs only during hospitalization should arouse suspicion that the patient is not adhering to her prescribed diet while at home; and (2) an abrupt decrease in insulin requirement usually is cause for concern of fetal welfare and calls for rapid reassessment of fetal and maternal status so that appropriate action based on the results of this reassessment can be taken.

Altered Renal Threshold

Alterations in the renal threshold for glucose plus the presence of additional reducing substances in the urine during pregnancy deserve discussion because various tests of urinary-reducing substances provide the patient with guidelines in determining alterations in insulin dosage on a day-to-day basis. It is, therefore, important to inform the patient that when she uses urine testing as a dosage guideline any given degree of glycosuria will, as a general rule, require the addition of a smaller amount of insulin than was the case prior to her pregnancy.

Daily Clinical Testing
